CHAPTER I

INTRODUCTION

Uncaria Schreber forms an easily recognisable genus, all species having a climbing habit and peduncles converted into recurved hooks as oustanding characters. (1) Formerly Adina Salisb., Mitragyna Korth., Uncaria Schreber, Nauclea L., Cephalanthus L., Saroocephalus Afz., Anthocephalus A. Rich., Breonia A. Rich. and Paracephaelis H. Bail. and other genera including Acrodryon Spreng., Metadina Bakh. f., Myrmeconauclea Merr., Paradina Pierre ex Pitard and Sarcopygme Setch. et Christoph. were placed in the tribe Naucleese. (2,3,4) According to differences in morphological features. Ridsdale excluded Cephalanthus, Mitragyna and Uncaria from the tribe Naucleeae; (5) Mitragyna and Uncaria are now placed in the sub-tribe Mitragynineae of the tribe Cinchonese. (5) Alkaloids from all ten species of the genus Mitragyna have been report, not all species of the closely related and larger genus, Uncaria, have been chemically investigated. (6) Some of the Uncaria alkaloids listed in the chemical literature originate from plant material of doubtful identity, and some are known to have arisen from the extraction of mixed collections. (43) In part. these difficulties may be attributed to the problems encountered in the identification of some of the individual Uncaria species. Difficulties in distinguishing between these species are reflected in the 120 specific names in the Index Keewensis which are now reduced to 34 in Ridsdale's recent revision. (5) They are arranged into seven

```
informal groups as illustrated in the following:-(5,7,10)
                                                w. cordata - f. cordata
                                                                f. sundaioa Ridsd.

           Relationships within Uncaria arranged as a dendrogram.
```

The genus <u>Uncaria</u> is widely distributed in tropical regions, its stronghold being South East Asia from Malaysia to the Solomon Islands; however, it is also located in other part of Asia, in Africa and South America. In Thailand most of <u>Uncaria</u> species are concentrated in the southern part. Craib reported that there were about 14 species of <u>Uncaria</u> growing in Thailand. In accordance with Ridsdale's recent revision, the species of <u>Uncaria</u> in Thailand are now reduced to 12 species. An alphabetical list of <u>Uncaria</u> growing in Thailand as recognized by (10)
Ridsdale is presented as follows:-

	Species	Distribution	eReference
1.	Uncaria acida (Hunt.) Roxb. var. acida		5 5
2.	U. attenuata Korth.	SuratThani, Chumpawn, Pattani	9
	(<u>U. salaccensis</u> Bakh.f. nom provis) "Khrua-See-Liam, เครือสีเหลียม	Nakornrachasima "	5
3.	U. borneensis Havil.	Peninsula	5 5
4.	U. canescens Korth.	Peninsula; Phuket, SuratThani	5

12.	U. scandens (Smith) Hutch.	Northern; MaeHongSorn, Northeastern; UdonThani,	5
	(<u>U. pilosa</u> Roxb.)	UdonThani, NawngKai	9

Uncaria homomalla Miq. belongs to group V, this group contains

nine species representing the Indo-China taxa which are geographically
(5,10)

and morphologically distinct from all the other taxa. Three

pyridino-indolo-quinolizidinone alkaloids, angustine, angustoline, and
(11,12)

angustidine, and four pentacyclic oxindole alkaloids, isopteropodine,
(25)

pteropodine, speciophylline and uncarine F have been isolated from

Uncaria homomalla Miq. leaves but no corresponding heteroyohimbine

alkaloids have been isolated. Environmental factors, for example, soil

and climatic conditions, may influence the production of alkaloids and

the types elaborated. Their rate of formation may also tend to fluctuate

during growth and development of the plant. In some species of the

neighbouring genus, Mitrhaum, the production of heteroyohimbines and

oxindole alkaloids has been demonstrated to be subject to seasonal (62-68)

variation. In the young leaves of Mitragyna parvifolia (Roxb.)

Korth., heteroyohimbines predominate; these give way to oxindoles having (62)

corresponding E-ring structure at later stages of leaf development.

Furthermore, it has been demonstrated that the interconversion of tetracyclic and pentacyclic alkaloids take place in Mitragyna parvifolia (62-68)

(Roxb.) Korth. Hence this thesis deals with examination of Uncaria homomalla Miq. leaves collected at regular monthly intervals from the same plant throughout the year which might give some indications of variation in seasons, ages, growth and development.
