

CHAPTER II

HISTORICAL

Botanical Aspects of The Menispermaceae

The Menispermaceae contains 73 genera and about 350 species, which are almost entirely tropical. There are 30 genera of this family occur in Asia, 22 in America, 30 in Africa and 10 in Australia to the Pacific.

The Menispermaceae is characterized by dioecious woody or sometimes herbaceous climbers, rarely erect shrubs or trees (*Cocculus* spp.); tubers sometimes present (*Stephania* spp.); sometimes producing exudate or rarely latex (*Fibraurea; Tinomiscium*). Wood often with concentric rings or arcs of vascular bundles separated radially by interfascicular rays, or vascular bundles in one ring; wood sometimes yellow. Young stem usually drying longitudinally striate, but young shoots often tendrilliform. Stipule absent. Leaf spiral, simple, often palmatinerved at base and sometimes peltate, or pinninerved at base and sometimes peltate, or pinninerved, margin usually entire, sometimes boardly crenate, sometimes deeply 3-5 lobed, petiole often swollen at base, sometimes also at apex, sometimes leaving a raised discoid scar on the stem. Inflorescences axillary or on defoliate branches or cauliflorous, solitary or fasciculate, various in form, often cymes, thyrses or pseudoracemes, branching of cymes rarely umbelliform (*Stephania* spp.), flowers rarely in disciform capitulum (*Stephania* spp.); female usually fewer flowered than male, female rarely with accrescent bracts (*Cissampelos* spp.) Flowers small, usually green, yellow or white, actinomorphic or female sometimes zygomorphic. Sepals usually in 1-2(-4) whorls of 3, or 1 whorl of 4, the outer whorl(s) smallest, imbricate but the innermost whorl sometimes valvate and sometimes connate, sepal rarely spirally arranged (*Hypserpa* spp.); in female sometimes reduced to 1 or 2. Petals mostly 3-6 in 1 or 2 whorls or 0, free or sometimes ± connate, usually smaller than the sepals, rarely larger

(*Sarcopetalum* spp.), the lateral edges or lobes often inflexed and sometimes clasping the opposite stamen, often glandular within, in female sometimes reduced to 1 or 2. *Stamen* mostly 3 or 6, sometimes 9 or up to about 40, often free and opposite a petal, or variously connate, sometimes forming a peltate synandrium, connective sometimes adaxially or abaxially thickened, rarely terminally prolonged (*Macrococcus* spp.); anthers introrse to extrorse with dehiscence longitudinal to transverse. *Staminodes* sometimes present in female, usually subulate, carpels free, usually 3 or 6, sometimes 1 or to 12, sometimes borne on a short gynophore; style terminal when present; stigma often sessile, reflexed and lobed or divided. *Pistillodes* 0 in male. *Ovules* 2 reducing to 1 in development, attached ventrally. Fruits of 1-6(-10) drupes sometimes borne on an enlarged globose, discoid or columnar carpophore which is rarely shortly branched (*Anamirta*, *Tiliacora*). *Drupes* sometimes narrowed at base into a stipe, style-scar terminal, ventral or close to base; exocarp membranous to coriaceous, mesocarp freshly; endocarp usually bony rarely papyraceous to crustaceous (*Pycnarrhena* spp.) rugose, tuberculate, spiny, ridged or variously ornamented on at least the dorsal surface, sometimes smooth or surface fibrous, usually with a condyle; i.e. a ventral sometimes hollow intrusion into the seed cavity around which the seed is curved, or a ventral groove, cavity or chamber; the condyle when hollow often 2-chambered and with 2 lateral or ventral apertures or condyle septiform or lamelliform, then sometimes centrally perforate. *Seed* often horseshoe-shaped; endosperm present or absent, sometimes ruminant, embryo usually either elongate and with semiterete or flattened contiguous cotyledons or flat and very thin with divaricate foliaceous cotyledons, sometimes broadly ellipsoidal with thick contiguous cotyledons, rarely cotyledons much folded (*Arcangelisia* spp.); radical very small (Forman, 1986).

There are 22 genera, and 51 species in Thailand; of which 9 species are endemic (Shown by asterisk). All of them are as follows:

1. *Albertisia papuana* Becc.

A. puberula Forman*

2. *Anamirta coccus* (Linn.) Wight & Arn.

[*Chung cha ling* (ចុងឆានិក), *Chingcha chali* (ចិងឆាតាចាតិ) (General)]

T. crispa (Linn.) Hook. f. & Thoms.

[*Boraphet* (បុរាណិត) (Central)]

T. siamensis Forman*

T. sinensis (Lour.) Merr.

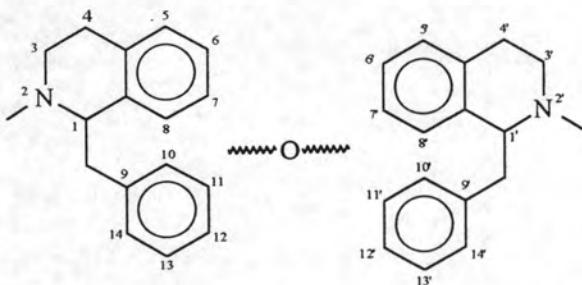

[*Ping kaling* (ពិងកលិក) (Northern); *Sali thao chali* (សិលិោចាតិ) (Central)]

(Forman, 1991)

Bisbenzylisoquinoline Alkaloids in Plants

The bisbenzylisoquinolines are the largest group of isoquinoline alkaloids. They are represented by approximately four hundred compounds which occur primarily in the families Berberidaceae, Menispermaceae, Monimiaceae and Ranunculaceae.

Bisbenzylisoquinoline alkaloids are built up of two benzylisoquinoline units linked by ether bridges.

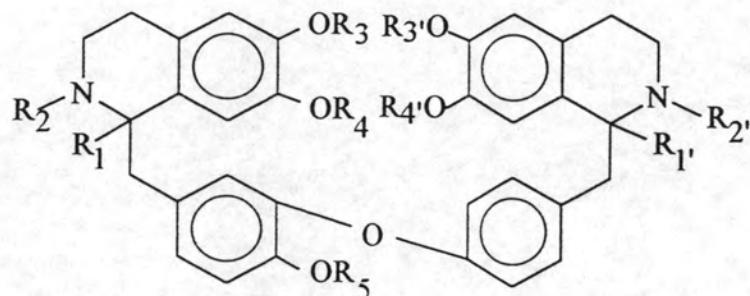

In addition to this ether linkage, methylenoxy bridging or direct carbon-carbon bonding is also found between the two benzylisoquinoline units (Guha and Mukherjee, 1979).

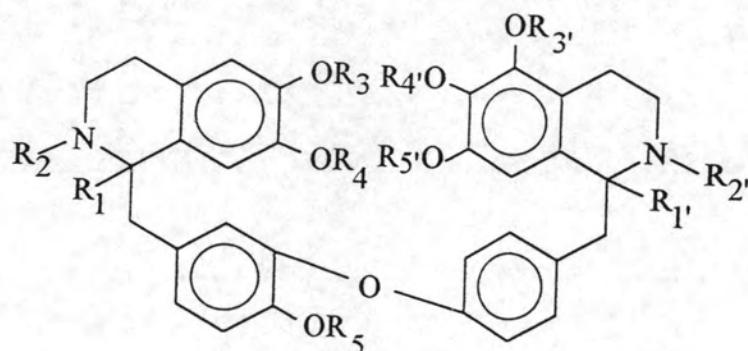

The bisbenzylisoquinolines have been classified into 26 types. These types can best be described by numerical system obeying the following rule:

1. The membering system for a bisbenzylisoquinoline half of a dimer is shown above.
2. Each benzylisoquinoline half of the dimer is described in terms of its oxygenation pattern, since only oxygenated positions are indicated. The more highly constitutes the left-hand side of the dimer. The two sets of numerical values are separated by a hyphen. In the case of head-to-tail coupling, the more highly oxygenated benzylisoquinoline is placed on top.
3. The symbols *, +, and ++ indicate the shared oxygens of diaryl ethers, and are placed at the upper right of the appropriate numbers.
4. Numbers between parentheses, appearing after the listing of the oxygenated sites, denote a direct carbon-carbon bound for the presence of a biphenyl linkage. Numbers between squared brackets, appearing after the listing of the oxygenated sites, indicate the terminals of a methylenoxy bridge.

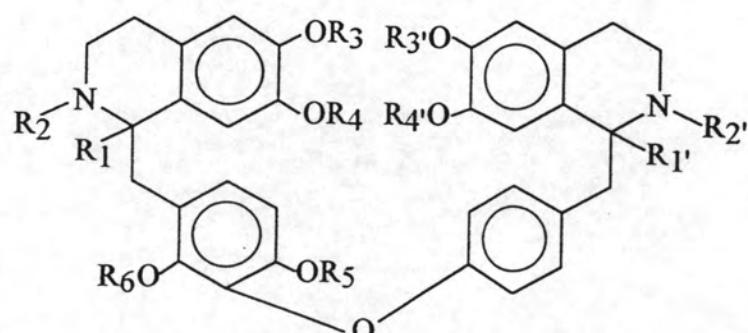

Using the above simple rules, the types of bisbenzylisoquinolines can be denoted as shown in table 1.

A complete list of the bisbenzylisoquinoline alkaloids follows table 2 and the sources of them in table3. This included structures showing configurations at the chiral centers. The bisbenzylisoquinoline alkaloids are represented by approximately four hundred compounds. The first comprehensive tabular review of the bisbenzylisoquinoline alkaloids was published by Guha et al. in early 1979 and then followed by Schiff, those were published in 1983, 1987 and 1991. But this present data in the table 2 is concerned with the literature through 1994.

Phytochemical investigation had been previously conducted on some *Pycnarrhena* species. Although the identified alkaloids proved to be mainly bisbenzylisoquinolines, but some of alkaloids are monomer of benzylisoquinoline or simple isoquinoline such as Magnoflorine(423), Pycnarrhine(424), respectively.

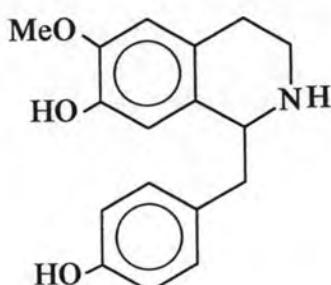

423 Magnoflorine

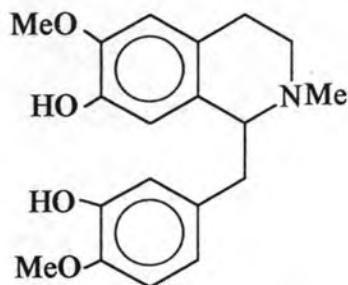

424 Pycnarrhine

Biosynthesis of Bisbenzylisoquinoline Alkaloids

The isoquinoline skeleton is incorporated into well over 1000 alkaloids and most of these compounds may be broken down into two broad categories depending upon whether they are derived biogenetically from the tetrahydroisoquinoline (\pm)-coclaurine(425) or (+)-reticuline(426). (\pm)-Coclaurine-derived alkaloids tend to dimerize to provide more than 250 different bisbenzylisoquinoline. The *in vivo* chemistry of (+)-reticuline(426), which possesses an additional oxygen in the bottom ring, differs in some important respects from that of (\pm)-coclaurine(425).

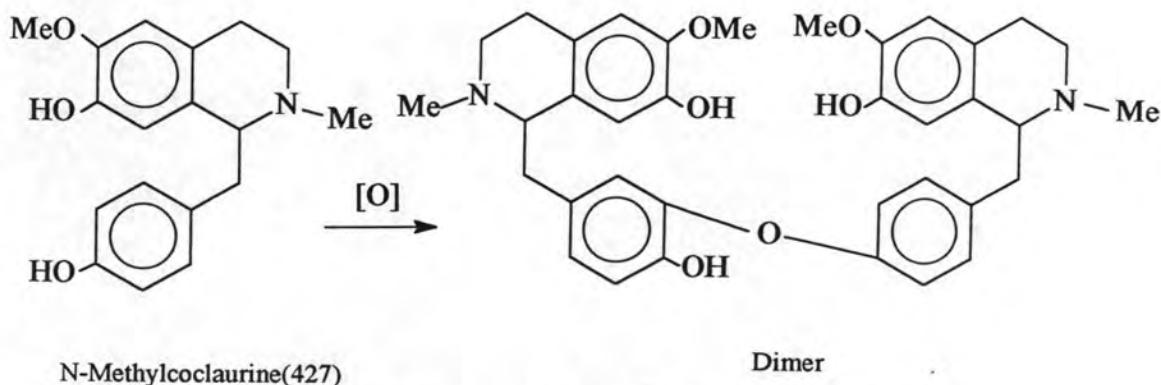

(\pm)-Coclaurine(425)

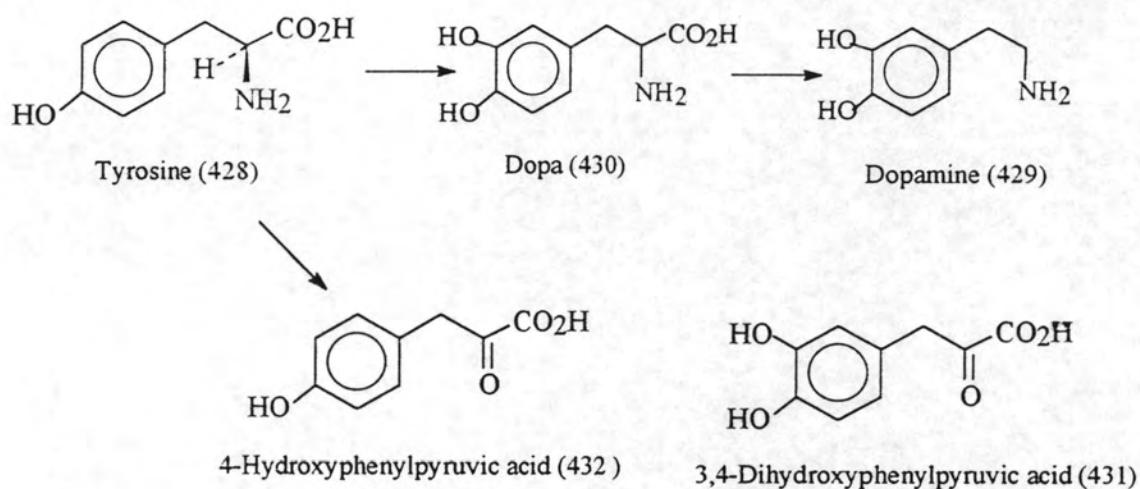

(+)-Reticuline(426)

In fact only nine bisbenzylisoquinolines are known that incorporate a reticuline moiety bounded to a coclaurine unit while a few of them were originated from bonding between two reticulines (Bruneton et al., 1983), but several of these alkaloids were shown to be derived by coupling of coclaurine or *N*-methylcoclaurine units (427) (Scheme 1).

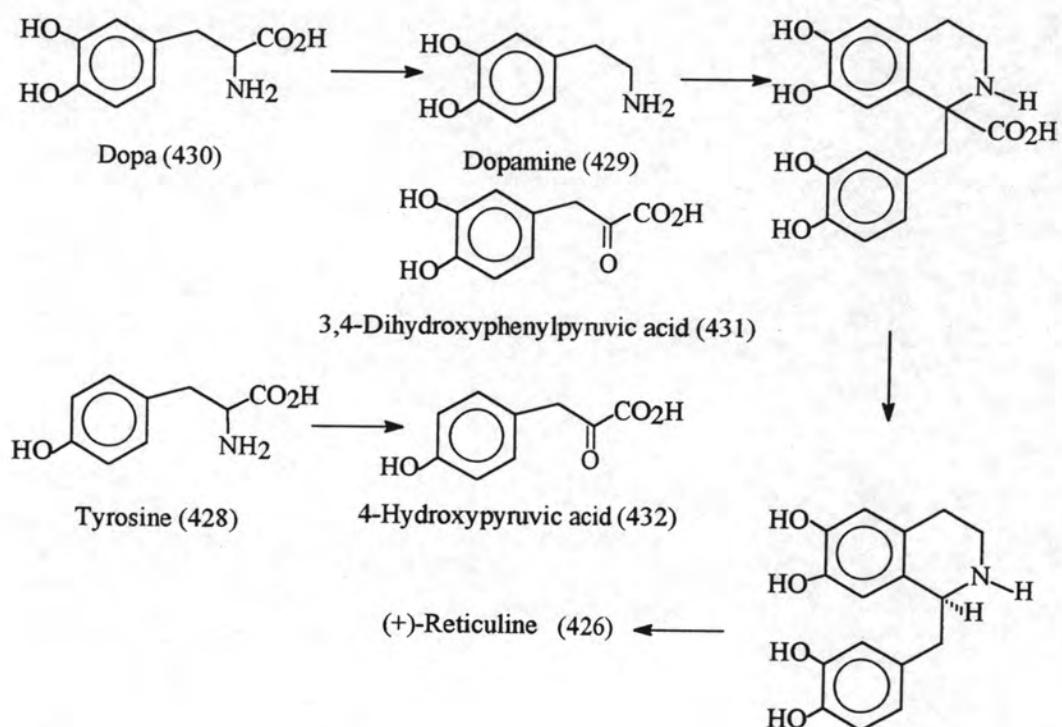

Scheme 1 The Formation of Bisbenzylisoquinoline alkaloid

The fundamental units are those for the formation of the benzylisoquinoline alkaloids with the addition of a single carbon atom which becomes c-8 of the skeleton. Thus two molecules of tyrosine(428) are involved, one proceeding to dopamine(429) via dopa(430), and the second to 3,4-dihydroxyphenyl pyruvic acid(431). (Scheme 2)

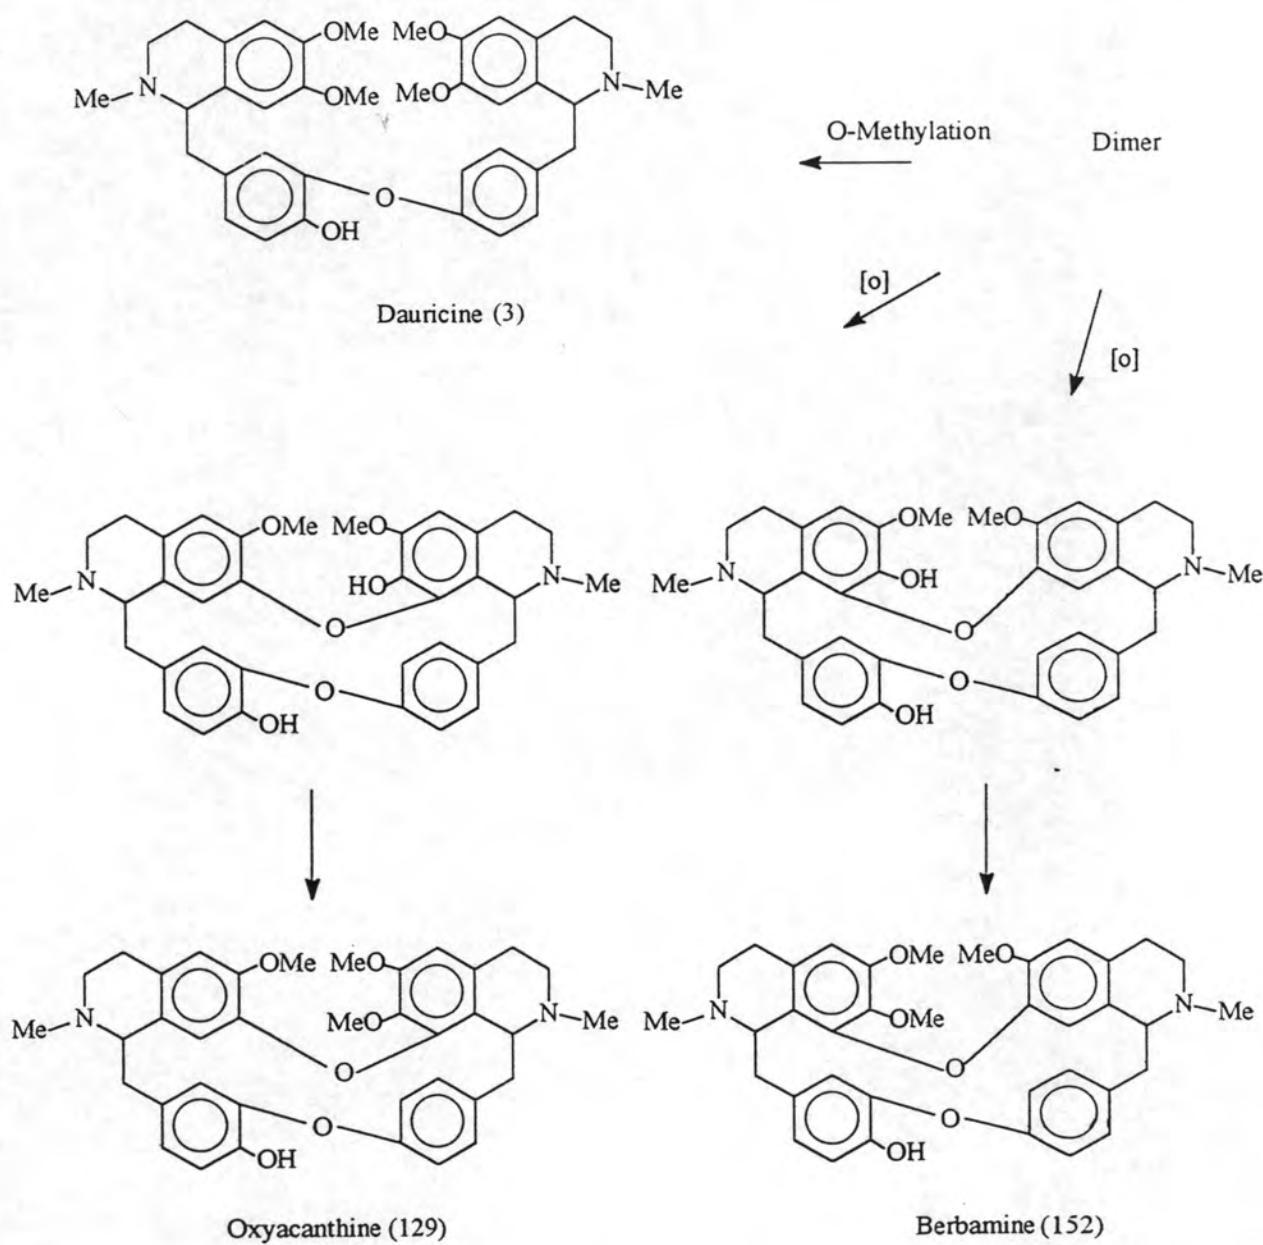

Scheme 2 The Biosynthesis of 3,4-Dihydroxyphenylpyruvic acid (431)

From feeding experiments, [$1-^{14}\text{C}$]dopa was incorporated into norlaudanosoline 1-carboxylic acid via dopamine. It is considered that 4-hydroxyphenylpyruvic acid(432), produced by oxidative deamination of tyrosine(428), is subsequently hydroxylated to afford 3,4-dihydroxyphenylpyruvic acid(431) and then was incorporated into norlaudanosoline 1-carboxylic acid to form (+)-reticuline(426) as follow (Scheme 3).

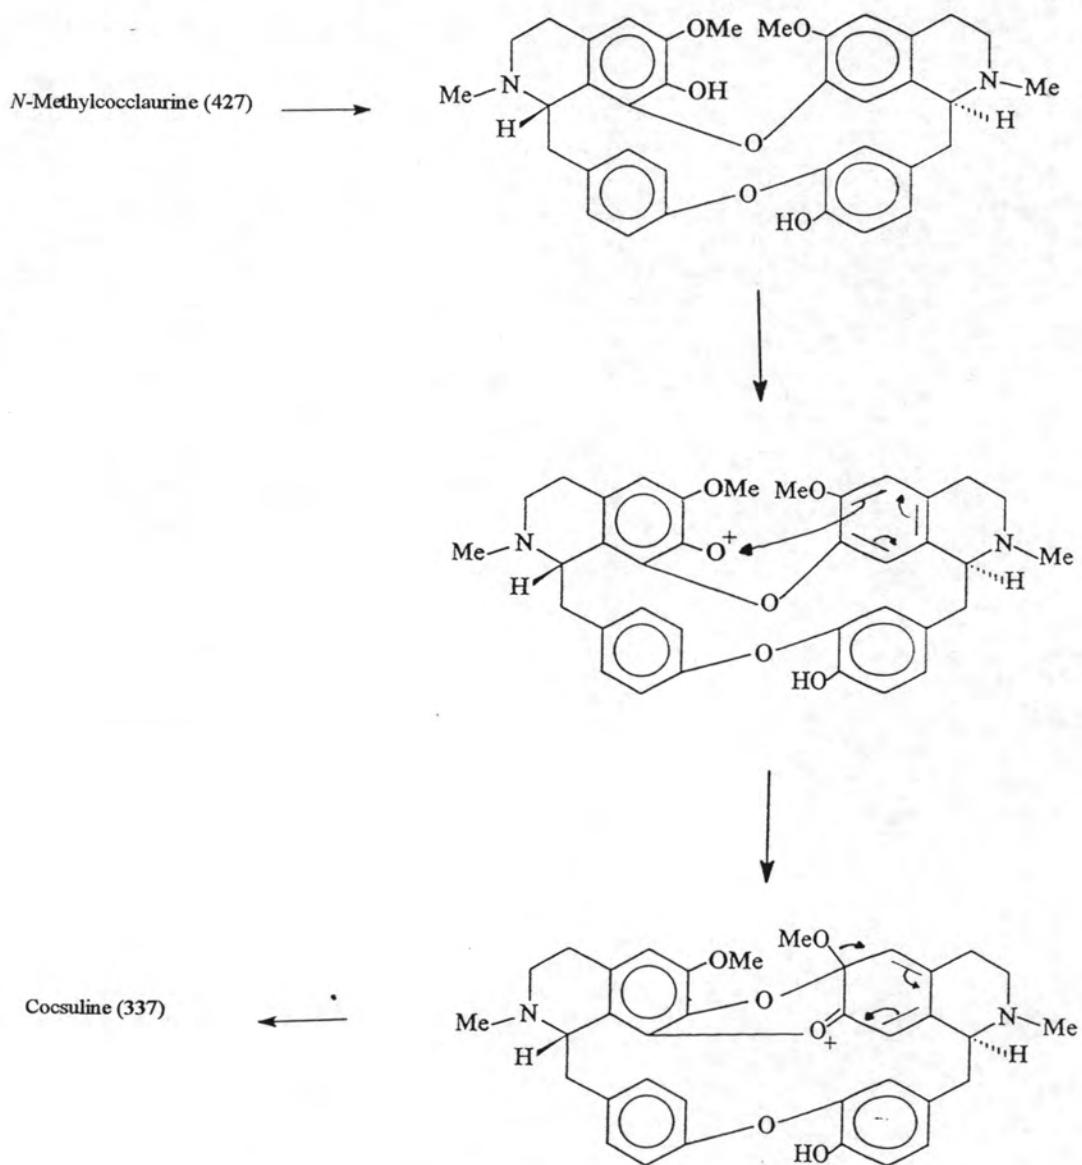

Scheme 3 The Biosynthesis of (+)-Reticuline (426)

In nature, bisbenzylisoquinolines are formed through the phenolic oxidative coupling of simple benzylisoquinoline such as *N*-methylcochlaurine(427), (+)-reticuline (426), as mentioned above. A logical, but so far hypothetical sequence that could lead to dauricine(3), oxyacanthine(129), and berbamine(152) would be as described in scheme 4.

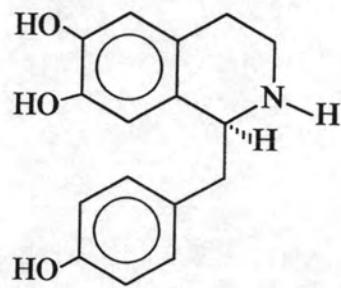

Scheme 4 The Biosynthesis of Oxyacanthine (129) and Berbamine (152)

As mentioned above, those are overall biosynthesis pathway of bisbenzylisoquinoline. After that, the detail of some experiments on *Cocculus laurifolius* D.C. with a combination of ^{14}C - and ^3H -labeled *N*-methylcoclaurine and related compounds substantiated the biosynthetic scheme shown for cocsuline(337).

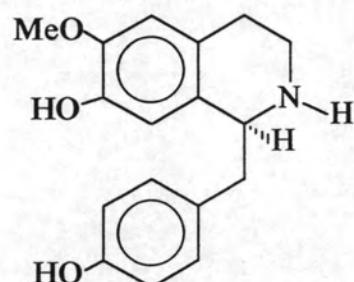

Scheme 5 The Biosynthesis of Cocsuline(337)

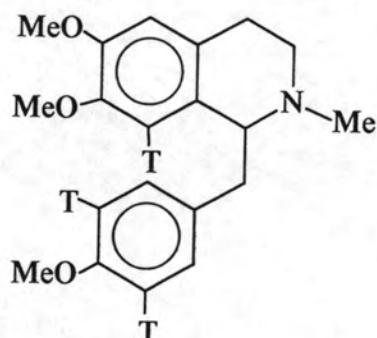

Tyrosine(429) was shown to be an efficient precursor of cocsuline(337), and the intermediacy of (*s*)-norcoclaurine(433), (*s*)-coclaurine(434) and (*s*)-N-methylcoclaurine was demonstrated by the following observations.

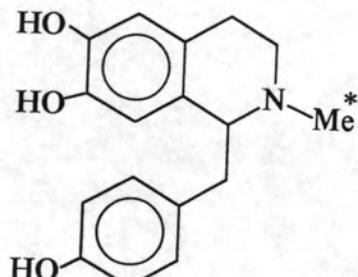

(S)-Norcoclaurine(433)

(S)-Coclaurine(434)

Tritium-Labelled (R,S)-O-Methylarmepavine(435)

14C-Labelled (R,S)-N-Methylnorcoclaurine(436)

Tritium-labeled (*R,S*)-O-methylarmepavine(435) was not incorporated, nor was ¹⁴C-labeled (*R,S*)-*N*-methylnorcoclaurine(436). Feeding the racemic resulted in appearance of only half of the total radioactivity in the isolated cocsuline(337), showing that only one enantiomer is utilized, and feeding of the enantiomers of *N*-methylcoclaurine(427), labeled with either 1-³H or *N*-¹⁴C, proved that it is the (*s*) form. (Brossi, 1987) It would be expected that the enzyme system involved in the relevant biotransformation would be stereospecific, and that only one of two optical isomers would normally act as a direct substrate.

A similar approach was used to establish the biosynthetic pathway in *Cocculus laurifolius* of cocsulinine(368) and tetrandrine(205). (*S*)-*N*-methylcoclaurine proved to be the precursor for both halves of the alkaloid.

In another study of isotetrandrine(173) biosynthesis, feeding experiments were done on *Cocculus laurifolius* D.C. It was shown that *Cocculus laurifolius* elaborates isotetrandrine(173) from (*R,S*)-*N*-methylcoclaurine and double labelling experiment with (+)-*N*-[¹⁴C]methyl[1-³H]coclaurine demonstrated that hydrogen atom at the asymmetric centre in *N*-methylcoclaurine(427) is retained in the bioconversion into isotetrandrine(173). So that it could rule out some hypothesis that the enantiomer are interconvertible via the dehydromethyl-coclaurinium ion (Bhakuni, Singh and Jain, 1980).

The biosynthesis of the diastereomeric biphenyl-linked alkaloids tiliacorine (189) and tiliacorinine(290) in *Tiliacora racemosa* Colebr. was studied by isotopic labeling. Labeled racemic norcoclaurine(433), coclaurine(425) and *N*-methylcoclaurine(427) were readily incorporated in to both alkaloids. The configurations of the asymmetric centers of tiliacorine(189) and tiliacorinine(290) were shown by separately feeding only one labeled enantiomer of *N*-methylcoclaurine(427). (*S*)- and (*R*)-*N*-methylcoclaurine were incorporated equally into tiliacorine(189), but

the labeled (*S*) form was converted 70 times more readily than the other enantiomer into tiliacorinine(290).

Stephania glabra (Roxb.) was shown to produce cycleanine(302) and *N*-desmethylcycleanine(305) via dimerization of both (*R*)-*N*-methylcoclaurine and (*R*)-coclaurine. The plant was proven to utilize *L*-tyrosine to biosynthesize the intermediate *N*-methylcoclaurine (Brossi, 1987).

The biosynthesis of the various bisbenzylisoquinoline alkaloid types is a fascinating area which has been little discussed. In addition, compounds having three diphenyl ether linkages pose even more stimulating academic problems.

Pharmacology of Bisbenzylisoquinoline Alkaloids

Bisbenzylisoquinoline alkaloids have several types of biological activities. There are two bisbenzylisoquinolines of pharmacologic significance, tubocurarine chloride and tetrandrine, and there has already been discussion concerning the antitumor activity of tetrandrine (Cordell, 1981).

(+)-Tubocurarine, one of the alkaloids of tube curare from Brazil and Peru, is often present in the arrow poisons used by South American Indians. It is usually isolated as the crystalline dichloride salt. When injected into the bloodstream, it quickly blocks neuromuscular action so that respiration ceases and death results. Muscle paralysis is actually achieved by blocking the action of acetylcholine on the end-plate region of the muscle fiber. A single paralyzing dose in man (3-9 mg) lasts almost a half hour. (+)-Tubocurarine chloride is used in abdominal surgery in very small doses as a complement to anesthetics since it causes paralysis of the abdominal muscles without stopping the natural movement of the intestines. It actually blocks the transmission of nerve impulses at the myoneural junction to skeletal muscle. The drug is ineffective when taken orally, probably because it does not penetrate the intestinal walls. This fact also explains why animals that have been killed with an injection of tube curare can be eaten with impurity(Shamma, 1972).

also explains why animals that have been killed with an injection of tube curare can be eaten with impunity(Shamma, 1972).

(+)-Tetrandrine has been of recent interest because it possesses significant activity against the Walker carcinosarcoma system, and the *d*-isomer was found to be almost as active as the racemate. It has been the subject of extensive preclinical toxicological studies. In addition to anticancer activity, (+)-tetrandrine has potent hypotensive and vasodilatory effects in several animal species. Other effects observed after intravenous administration include antipyresis, anti-inflammation, and histamine liberation from mast cells. Nephrotoxicity and hepatotoxicity in monkeys and dogs have also been observed(Cordell, 1981).

The pharmacological action and effect reported in the studies of bisbenzylisoquinoline alkaloids are listed in table 4.

Table 4 Pharmacological Activity of Bisbenzylisoquinoline Alkaloids

Alkaloids	Pharmacological Activity	References
Antioquine (59)	Antiprotozoal Muscle relaxant	Schiff, 1991 Schiff, 1991
Aromoline (90)	Antimalarial	Schiff, 1991
Berbamine (152)	Antiprotozoal Hypotensive Hair tonic, Prevention of alopecia Inhibit natural killer cell cytotoxicity Inhibit platelet aggregation Immunostimulant Antileukopenic Antisilicotic	Schiff, 1991 Brossi, 1987; Schiff, 1991 Schiff, 1987
Berbamunine (1)	Spasmolytic	Brossi, 1987
Cepharanoline (94)	Membrane-modifying activity	Schiff, 1991
Cepharanthine (95)	Anti-inflammatory Anticoagulant Antidopaminergic effect Immunomodulatory effects Lipid peroxidation inhibitory effect Membrane modulator Antineoplastic activity Antihistamine Inhibit platelet aggregation Antitumor Antimicrobial Antileukopenic	Schiff, 1991 Brossi, 1987
Cocsuline (337)	Antiprotozoal	Schiff, 1991
Cocsulinine (368)	Active on human carcinoma	Brossi, 1987
Curine (319)	Muscle relaxant Antitumor	Brossi, 1987 Schiff, 1987
