Project Title: Fracture system of Loei Fold Belt along highway no. 2196 of
Khao Kho district, Phetchabun province.

Researcher: Poorinut Thipo

Advisor: Associate Professor Pitsanupong Kanjanapayont, Dr.rer.nat.

Department: Geology, Faculty of Science, Chulalongkorn University

Abstract

The Loei Fold Belt is complex structural zone. It caused by Sibumasu sub-continent subducted from east to west into Indochina in Early Triassic. This study focused on geological characteristic and evolution of Loei Fold Belt along highway no.2196 of Khao Kho district, Phetchabun province. From field structural geology and micro-structural data analysis, there are 2 main trend fractures which took place in tuff. Moreover, minor related joint sets were founded in each main fracture. The first set is in the NE to SW direction and has W to NW dip direction. The second set is also in the NE to SW direction but has E to SE dip direction. From their relationship, the first trend has off-set from effect of the second trend. So, the second trend is younger than the first trend. The evolution of them can be separated in to 2 stages. Stage 1 took place in Early Triassic which was the beginning of E-W compression and made fold belt along 2 continental margins. Stage 2 took place from Oligocene to Miocene. It was extension phase in this stage from the effect of India collided with Eurasia.

Acknowledgements

First of all, I would like to give my appreciation for the best guidance, teaching and lots of helping to Assoc. Prof. Dr. Pitsanupong Kanjanapayont who is my super advisor throughout my student life in department of geology. Over past 1 year, I learnt a new vision which brought me understand more in geology field and got a new experience from you. I don't know where else I can find all this wonderful experience.

I would like to extend my appreciation to Dr. Abhisit Salam, Dr. Sukhonmeth Jitmahantakul, Dr. Sumet Phantuwoongraj and another professor in my department for opportunities and assistances entire my student life and my project.

I would like to say thank you for all staffs in the department for helping me about documents, technical works and facilities since I've studied in this department.

I would like to express my special thanks to Khanitpong Aiemsintorn, Nutchapol Charnsiri, Krittanol Naewboonnien, Manunchaya Chongsutakawewong and Ratchaneekorn Thepkunchon for helping me collected field data.

I also would like to thanks for friendships to my friends in department for helping, supporting and motivating together over past 4 years.

Finally, I would like to say special thanks to my family for every support since the first step I came to Chulalongkorn University.

Chapter 1 Introduction

Chapter 1

1.1 Introduction

Structural geology in Thailand is affected by the two plate tectonic events. First event was in Triassic. Sibumasu sub-continent, which can be comparable with Shan-Thai (Bunopas, 1981), collided with Indochina sub-continent (Metcalf, 2011). The effect from this event makes the fold belts in the boarder of 2 sub-continents. They are Loei Fold Belt, in the east of Nan Suture, and Sukhothai Fold Belt, in the west of Nan Suture (Bunopas, 1981). Next, the second event was in Oligocene to Miocene. The India plate subducted along the Sumatra and passing northwards trough the Myanmar. The effect from the second event made the subduction roll back and Tertiary basins in Thailand (Morley., 2001).

So, the Phetchabun province is the affected area from the tectonic events because it has Loei Fold Belt and Phetchabun basin, one of Tertiary basins. This study focuses on the structural geology in terms of fracture systems to find the characteristic, relationship and analyze evolution of fracture in the Loei Fold Belt along highway no. 2196, Khao Kho district, Phetchabun province.

1.2 Objective

- 1.) To study the characteristic of fracture system at the study area
- 2.) To study the evolution of fracture system at the study area

1.3 Scope of the research

This research focus on the fracture systems by observing outcrops and collecting data from them. The data are collected along the highway no. 2196, Khao Kho district, Phetchabun province.

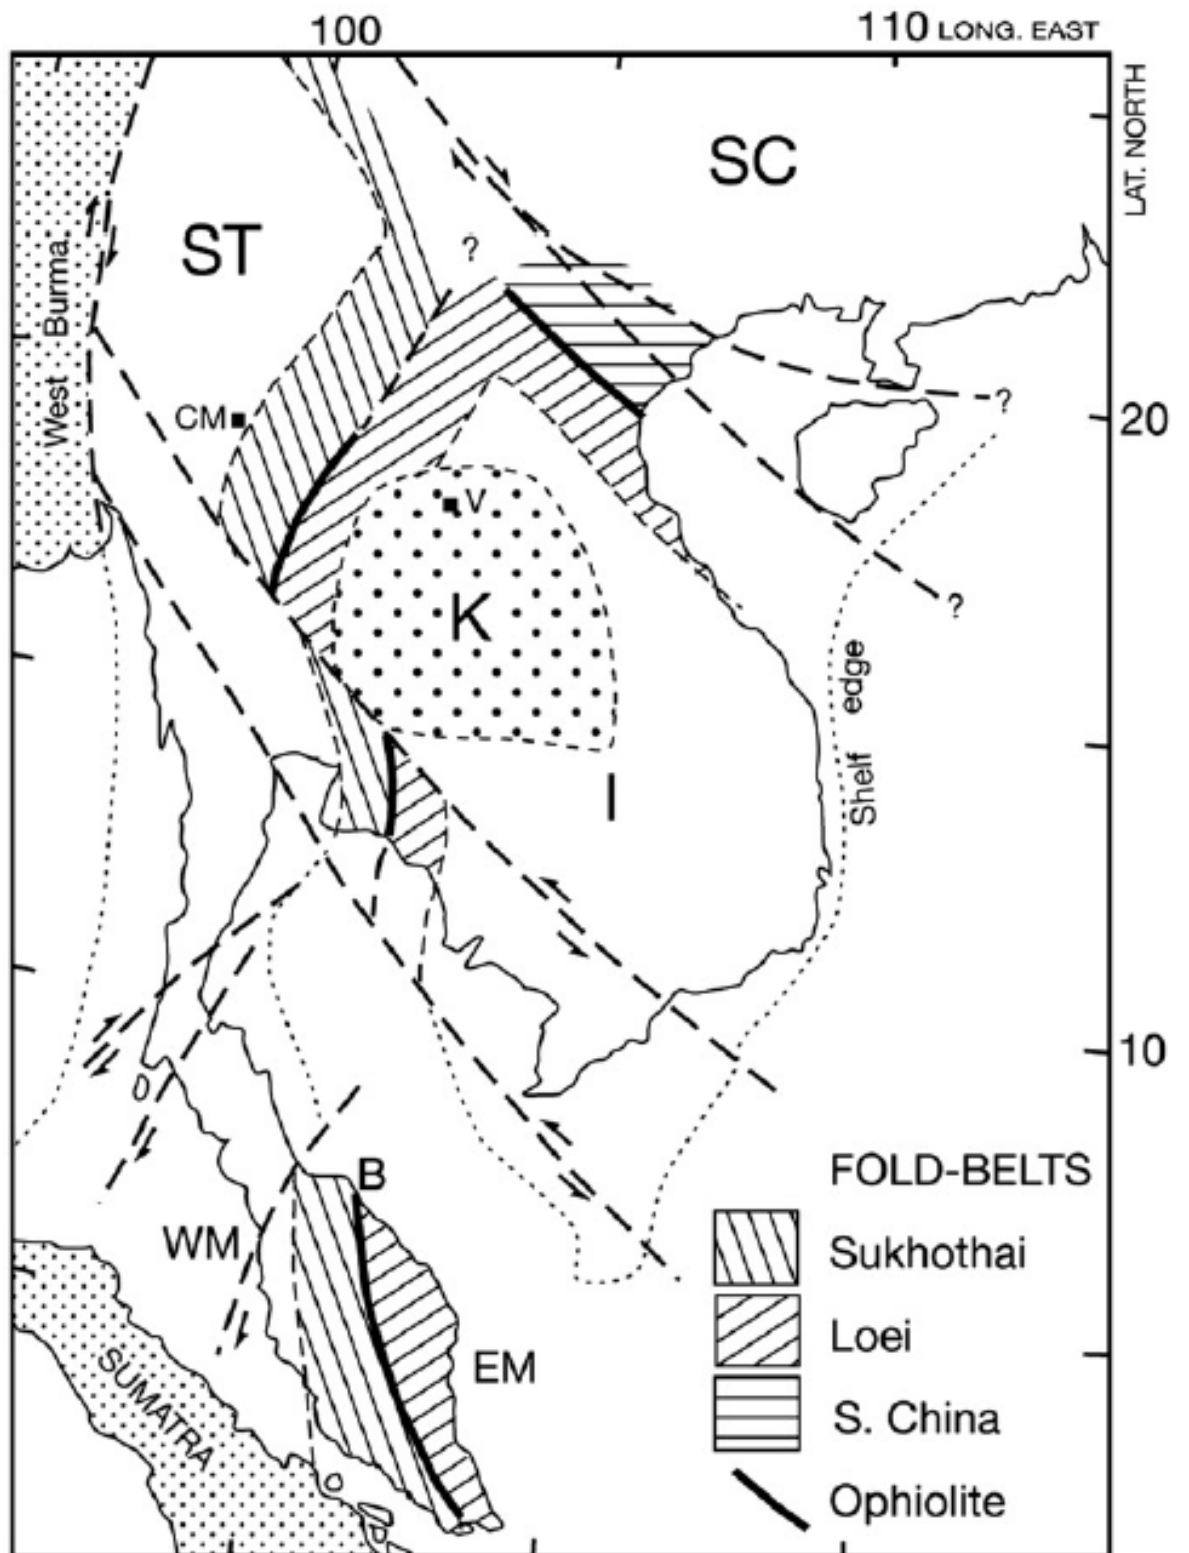

Fig 1.1 The boundary of Shan-Thai (SC), Indochina (I), Khorat Plateau (K), Loei Fold Belt and Sukhothai Fold Belt (Modified by Metcralfe, 2011)

1.4 Tectonic setting

Thailand composes of two major sub-continents. There are Sibumasu, which can be comparable with Shan-Thai (Bunopas, 1981), and Indochina. They collided during the Indosinian Orogeny after the subduction of the Paleo-Tethys Ocean that took place in the Devonian-Triassic (Sone & Metcalfe, 2008). The evidence of the collision is the two suture zones, Nan-Suture and Srakeaw sutures, laying along N-S trending.

In the Middle Devonian, the Paleo-Tethys started spreading. Then, the Tethys subducted under Indochina around the Late Carboniferous or Early Permian. It formed a magmatic arc along the western margin of Indochina called Sukhothai Arc. Moreover, this rapid subduction made the back-arc basin in the Early Permian. The back-arc closed in the Late Permian by the compression phase. The Sukhothai Arc became the part of Indochina during the closing of back-arc. The Paleo-Tethys continue subducted until the Late Triassic. The Sibumasu collided with the west of The Indochina. It built the major mountain range (Indosinian Orogeny). In the Lastest of the Triassic, Paleo-Tethys completely subducted into Indochina. This event made magmatism in Sukhothai Arc inactive (Sone & Metcalfe, 2008).

The collision between India and Eurasia plate was in Eocene to Neogene, also called the Himalayan Orogeny. The collision made the inversion of strike-slip fault in Thailand and resulted in regional uplift of the Korat Plateau, NE Thailand). The effected of strike-slip fault in Thailand ceased in 30 ma (Watcharanantakul, 2001). So, the Tertiary basin in Thailand caused by subduction rollback from the effected of India increase angle of subduction. It subducted steeply from Sumatra to northwards. (fig 1.3)

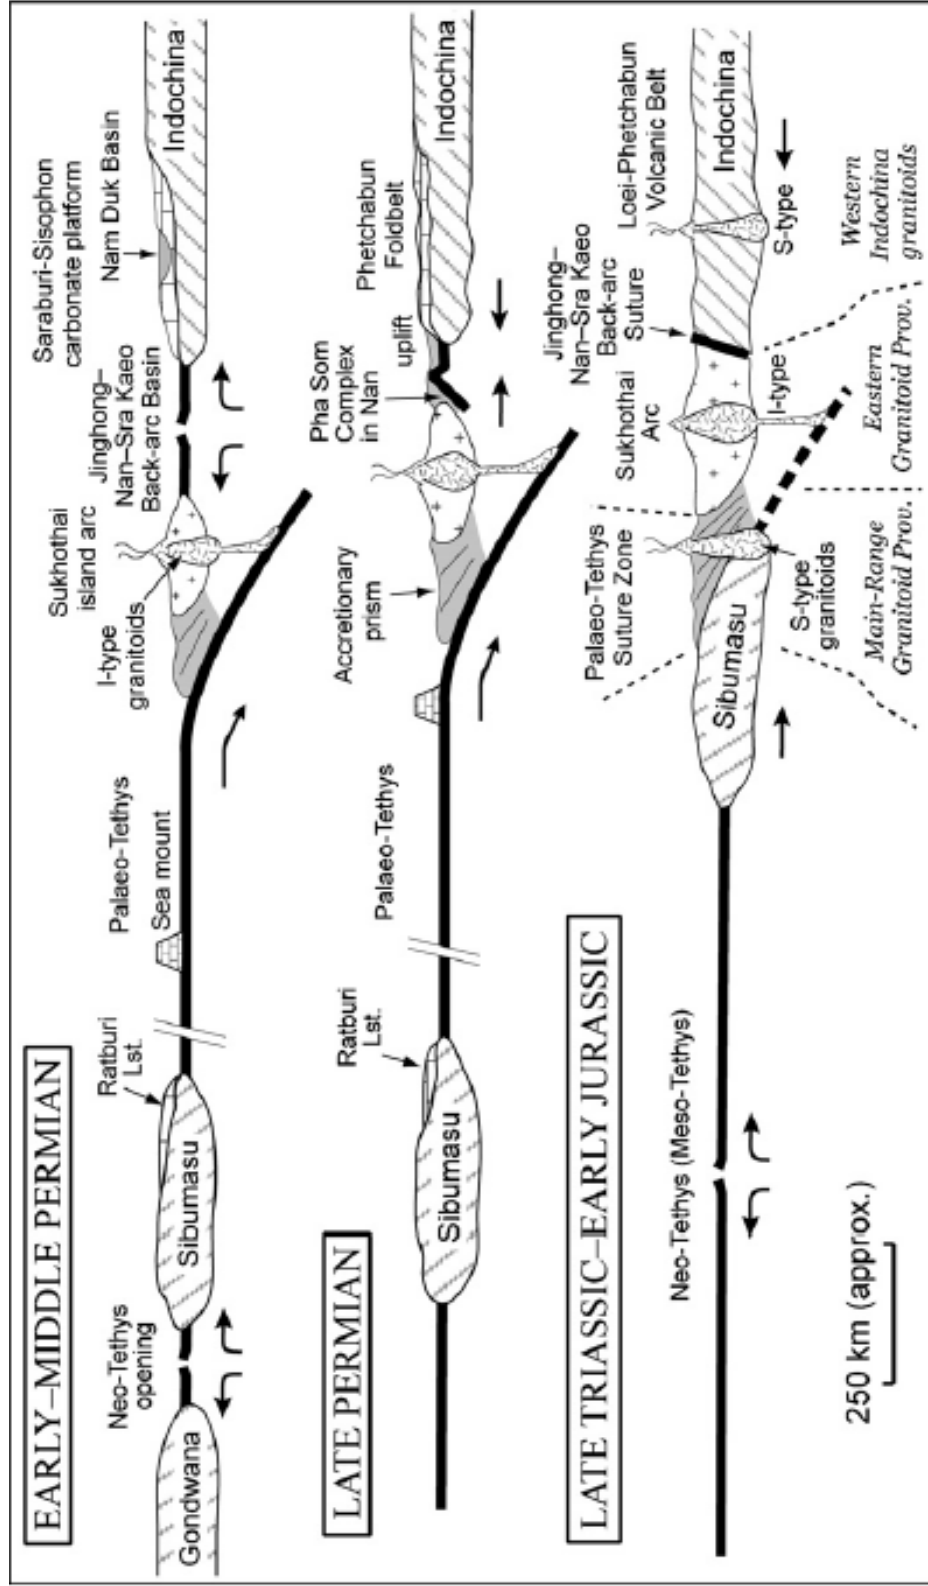

Fig 1.2 Tectonic evolution of mainland SE Asia during the Permian to Early Jurassic, with respect to the formations of the Palaeo-Tethys Suture Zone and the Jinghong-Nan-Sra Kao back-arc Basin suture. Vertical scale arbitrarily exaggerated (Sone and Metcalfe, 2008)

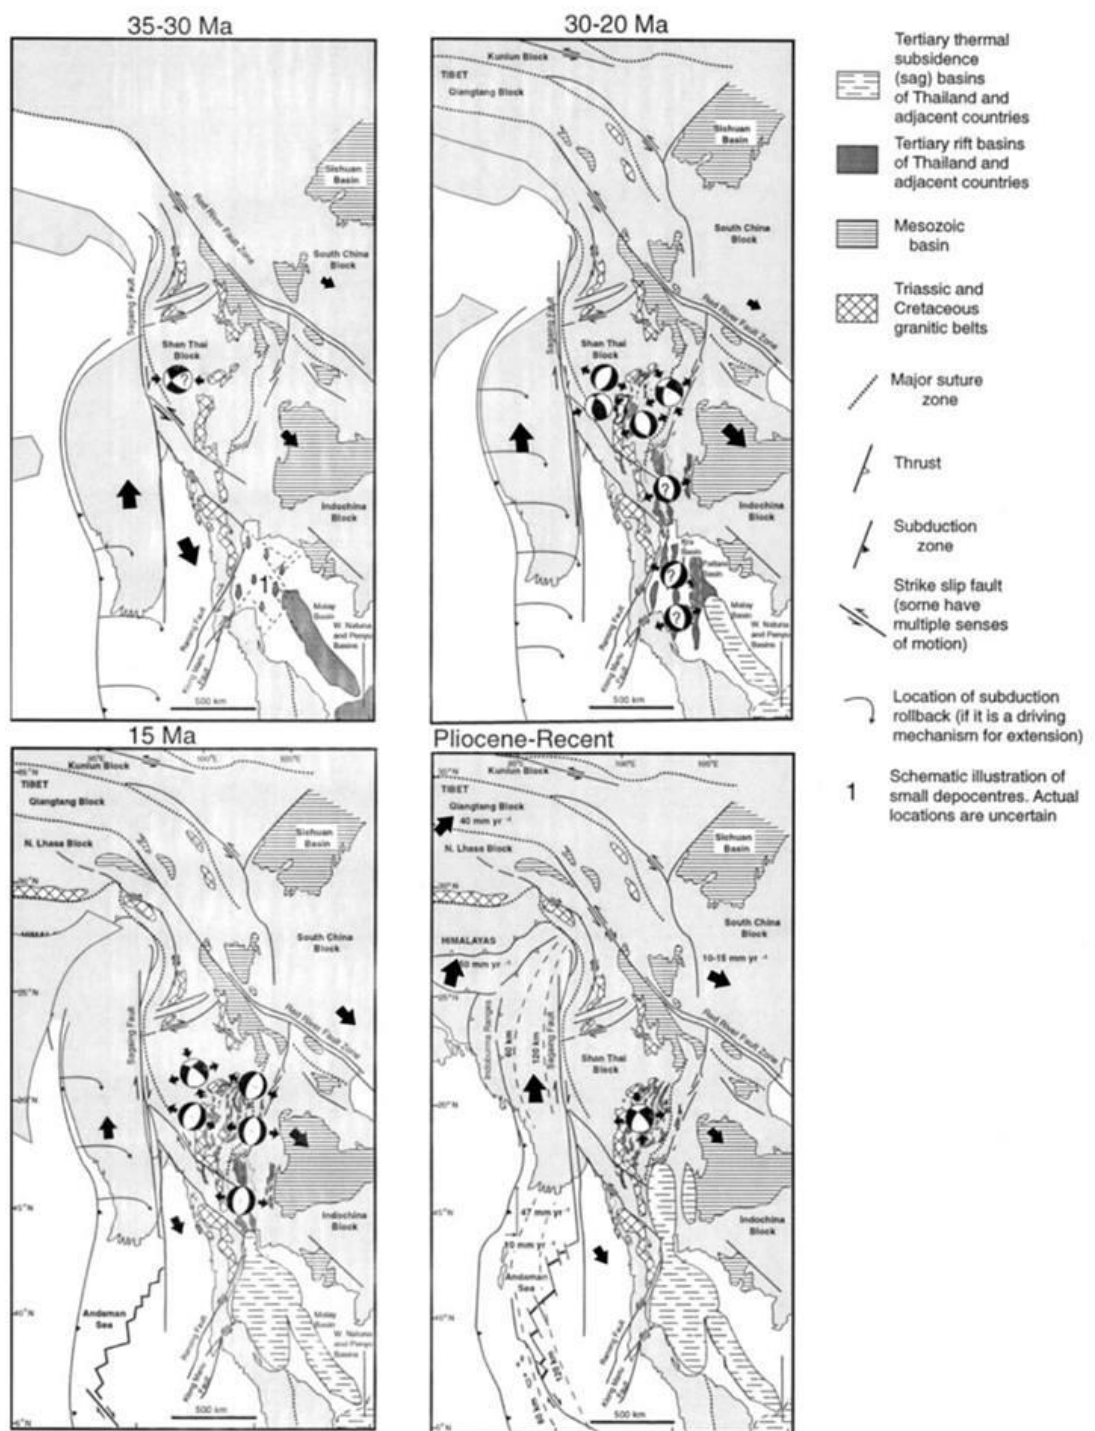

Fig 1.3 Geological evolution of SE Asia from the Oligocene to Present (Morley, 2001)

Chapter 2 Geological background and Methodology

Chapter 2

2.1 Geology in the study area

The study is in the western border of Indochina sub-continent. From the relationship between location and geological map from the Department of Mineral Resources (2010) defines the rocks in the study area into 2 main formations. There are Huai Hin Lat formation (TRhl) and Phu kradung formation (Jpk).

The Huai Hin Lat formation is in the eastern most of the study area (2007). It presents conglomerate, limestone conglomerate, grey to dark grey sandstone and siltstone (Iwai, 1964). The depositional age is Triassic from the dating data of its plant remnant (Konno and Asama, 1973), pollen and spores (Haile, 1973) and also vertebrate faunas. The depositional environment of this formation is fluvio-lacustrine environment indicated by fossils, which are fish fragment, turtle, amphibian and reptile. Chonglakmani and Sattayarak (1978) classified formation into 5 members. There are Mo member, Phu Hi member, Dat Fa member, Sam Khaen Conglomerate member and Pho Hai member.

The Phu kradung formation presents maroon siltstone, claystone and sandstone with greenish-grey calcareous conglomerate (Chaodumrong, 2013). From the bone fragments dating suggested the age that the formation is Middle to Upper Jurassic. Moreover, the depositional environment of this formation is fluvial deposit. Indicating from the upward sequence from top to bottom of conglomerate and channel sandstone to crevasse-splay facies and floodplain at the top.

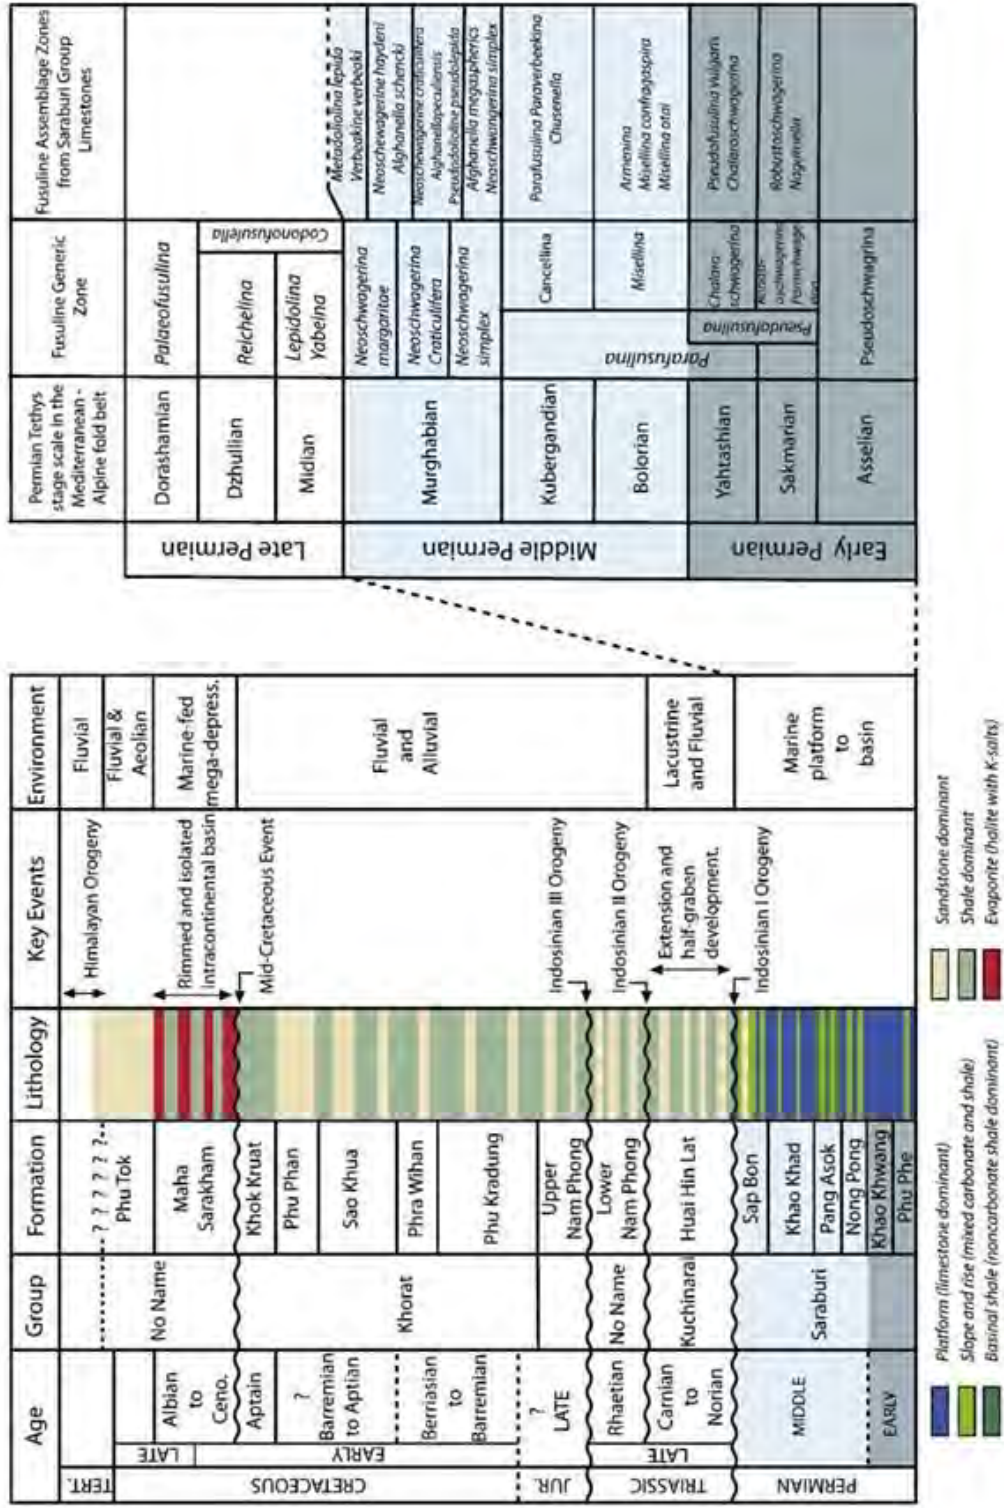

Fig 2.1 Regional stratigraphy and the fusulinid assemblage zones used for age subdivision (Warren et al., 2014)

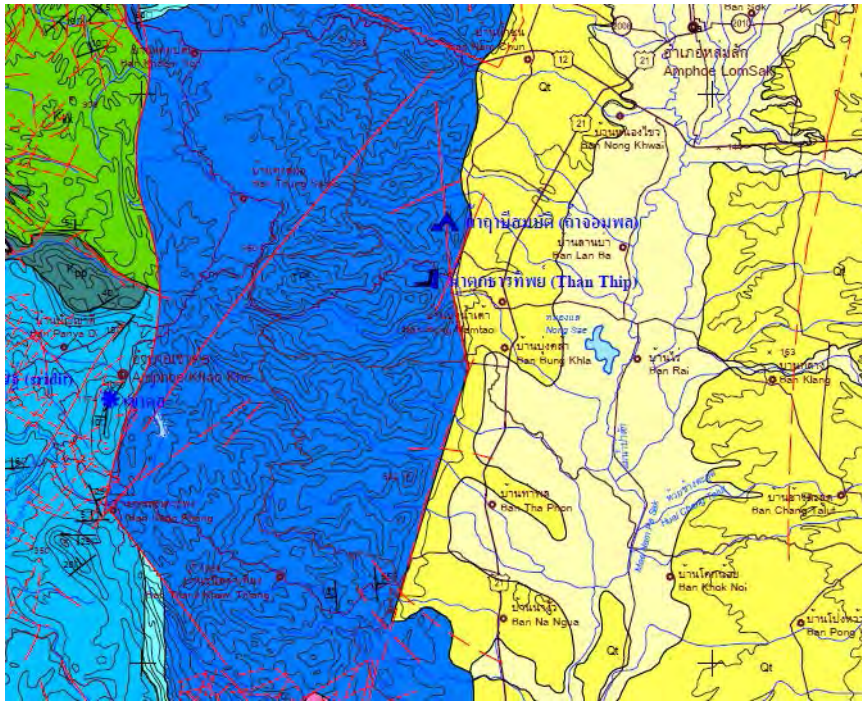

Fig 2.2 Geological Map (DMR, 2009)

Fig 2.3 Geological Map (DMR, 2007)

2.2 Fracture

Fracture can be normally found in the rocks. If we can collect them into a group, it will be fractures system which are developed from one or more tectonic event (Peacock, 2017). He can be divided into a group from their trend, type, and age. He can determine the relationship of them from these following.

2.2.1 Type of fractures

- 2.2.1.1 **Extensional fractures** or opening-mode such as joint, vein, dykes.
- 2.2.1.2 **Contractional fractures** or closing- mode such as stylolite, compaction band.
- 2.2.1.3 **Shearing-mode fractures** such as faults, deformation band.
- 2.2.1.4 **Combined fractures** which involve two modes above such as compaction shear band

2.2.2 Geometry and Topology

The natural fracture can be divided into geometry and topology from these following.

- 2.2.2.1 **Geometry** has 5 types (Fig) . There are isolated, approaching, abutting, branching and cross-cutting
- 2.2.2.2 **Topology** has 3 types from the node. There are I- node, Y- node and X-node.

2.2.3 Relative age

He identified the initial and subsequence fractures which we consider from cross-cutting relationship and displacement.

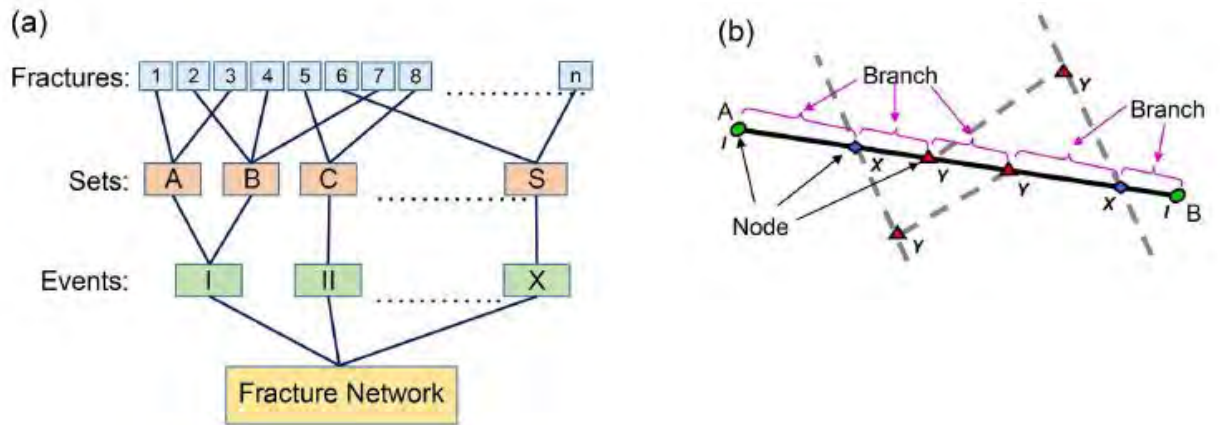

Fig 2.4 Fracture networks and interactions. (a) Fractures (1... n) can be divided into different sets, which may have been formed in a series of different events. (b) Fractures meet at nodes between which the fractures can be divided into branches (Peacock et al., 2018)

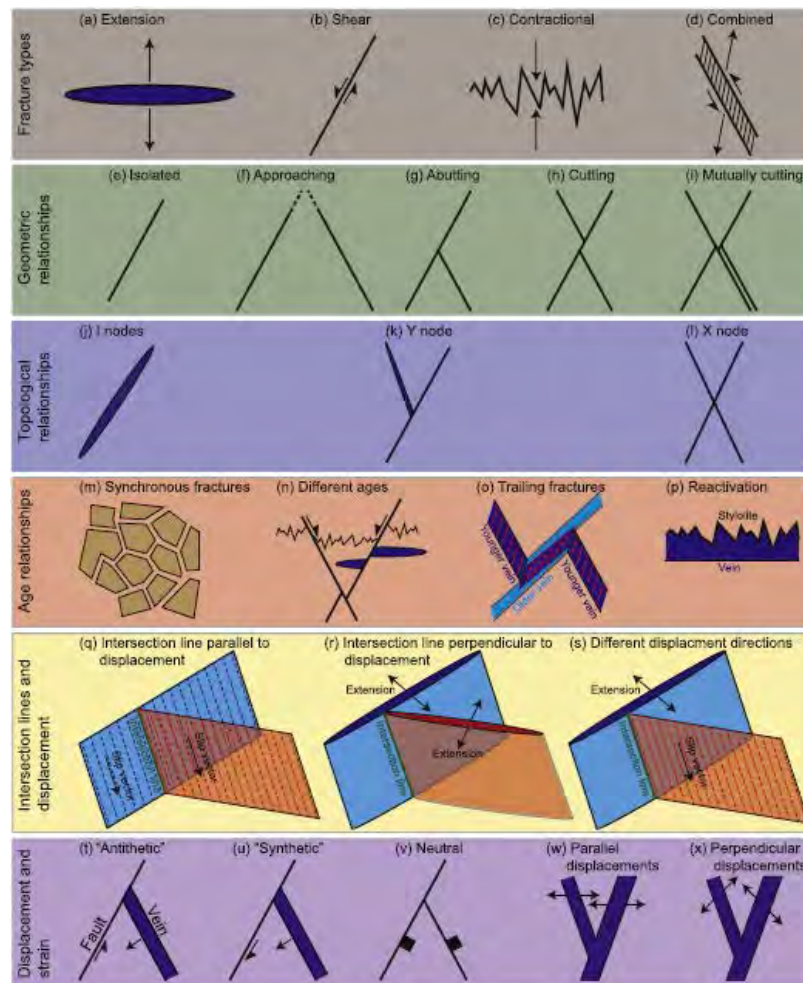

Fig 2.5 Classification of intersecting fractures, generalising the scheme for interacting faults (Peacock et al., 2018)

2.3 Methodology

The methodology of research can be divided into 6 main parts.

- 1.) Literature review
- 2.) Basic data collecting
- 3.) Field exploration
- 4.) Data analysis
- 5.) Discussion and conclusion
- 6.) Presentation and report writing

2.3.1. Literature review

Previous studies and reports about structural geology and Tectonics were reviewed especially. In addition, the program and data collecting method which are suitable for field exploration and interpreting data were favorable tested and practiced. For example, illustrator, ArcMap, Grapher, GeoRose.

2.3.2. Basic data collecting

The basic data which used in this study is collected from website. There are Geological maps 1:250000 of Phetchabun province from Department of Mineral Resources (2007 and 2009) and the digital elevation map in the study area.

2.3.3. Field exploration

The 8 road-cut outcrops were collected the structural feature and general geological data, which are bedding plane, fault plane, joint, mode of fracture and others, by taking photo and measuring data. The individual outcrop was identified location by UTM system and plotted into the final maps.

2.3.4 Data Analysis

All data from the field were analyzed in the programs. After that, the data from the programs was interpreted again to diagnose the structural geology in the study area and found the relationship of fractures of each station.

2.3.5 Discussion and conclusion

Collect all analyzed data to discuss in term of structural geology, which are structural of fractures and evolution model of fractures in the study area. They were discussed with the related studies and previous works and conclusion respectively.

2.3.6 Presentation and report

Fig 2.6 outcrop at the study area

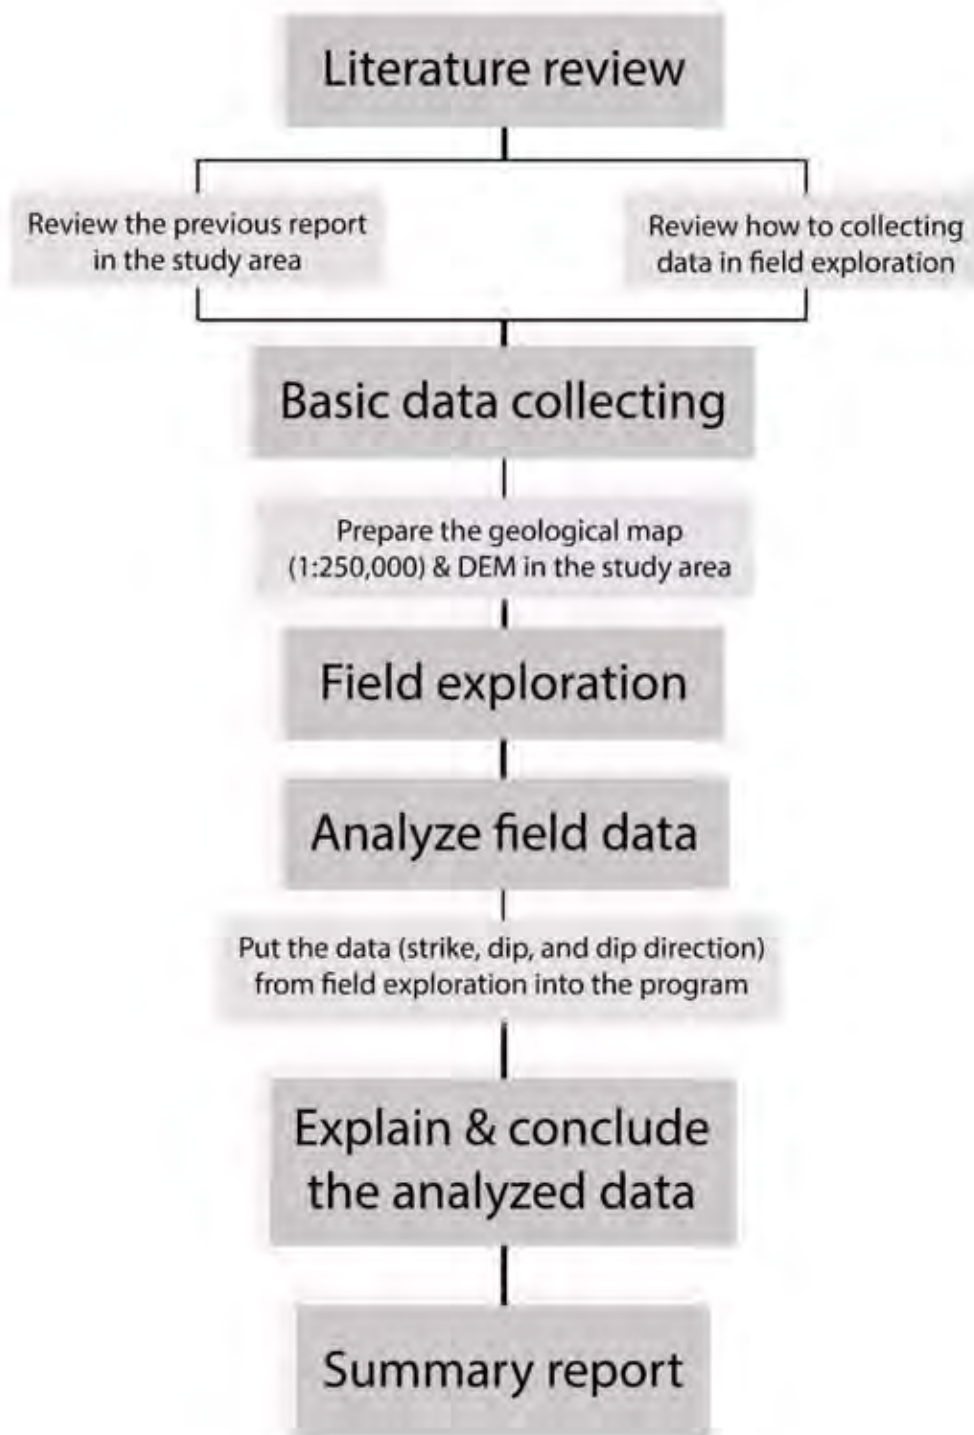

Fig 2.7 Researcher's work flow

Chapter 3 Results

Chapter 3

The result of 8 road-cut outcrops, from east to west along highway no. 2196, from field exploration. So, they can be divided into 2 parts, which are Lithology and Structural geology.

Fig 3.1 Digital Elevation Map (scale 1:15 m) of the study area. Low area is green and high area is pink

3.1 Lithology

The lithology along the road that we collect data is grey to black tuff. These rocks laid down in the N-S trends. Their beds are sub-vertical to vertical (very steep dip angle) and has approximately 10-30 cm thick (Fig. A and B). Their clasts are hornblende, plagioclase and some pyroxene. They also poorly sorted, low sphericity and angular to sub-angular roundness (Fig. C and D).

Fig 3.2 Rock sample and bedding in the study area. (a) and (b) show bedding of rocks in the study area. (c), (d), (e) and (f) are rock sample of study area

From the results in the thin section showed that these rocks have hornblende 25– 30%, plagioclase 55%, chlorite 15% and olivine 1% or less. In addition, they showed opening fractures which is filled by silica and plagioclase.

Fig 3.3 Thin sections. (a), (c) and (e) are PPL. (b), (d) and (f) are XPL

Fig 3.4 Thin sections. (a), (c) and (e) are PPL. (b), (d) and (f) are XPL

3.2 Structural geology

3.2.1 Fracture

Almost of the rocks from the field observation have 2 main trends, which are North to South and Northwest to Southeast direction, and also found the 2 joint sets in the same trends. The fracture of each station is presented in the following below.

Station 1

Station 1 is located in the eastern most of the study area. Outcrop is more than 10 meters long and 3 meters high. Fractures in this station are East to West direction. There are opening mode fracture, joint sets, and sliding mode fracture, Trust fault. The Fault has dip angle around 15 to 30.

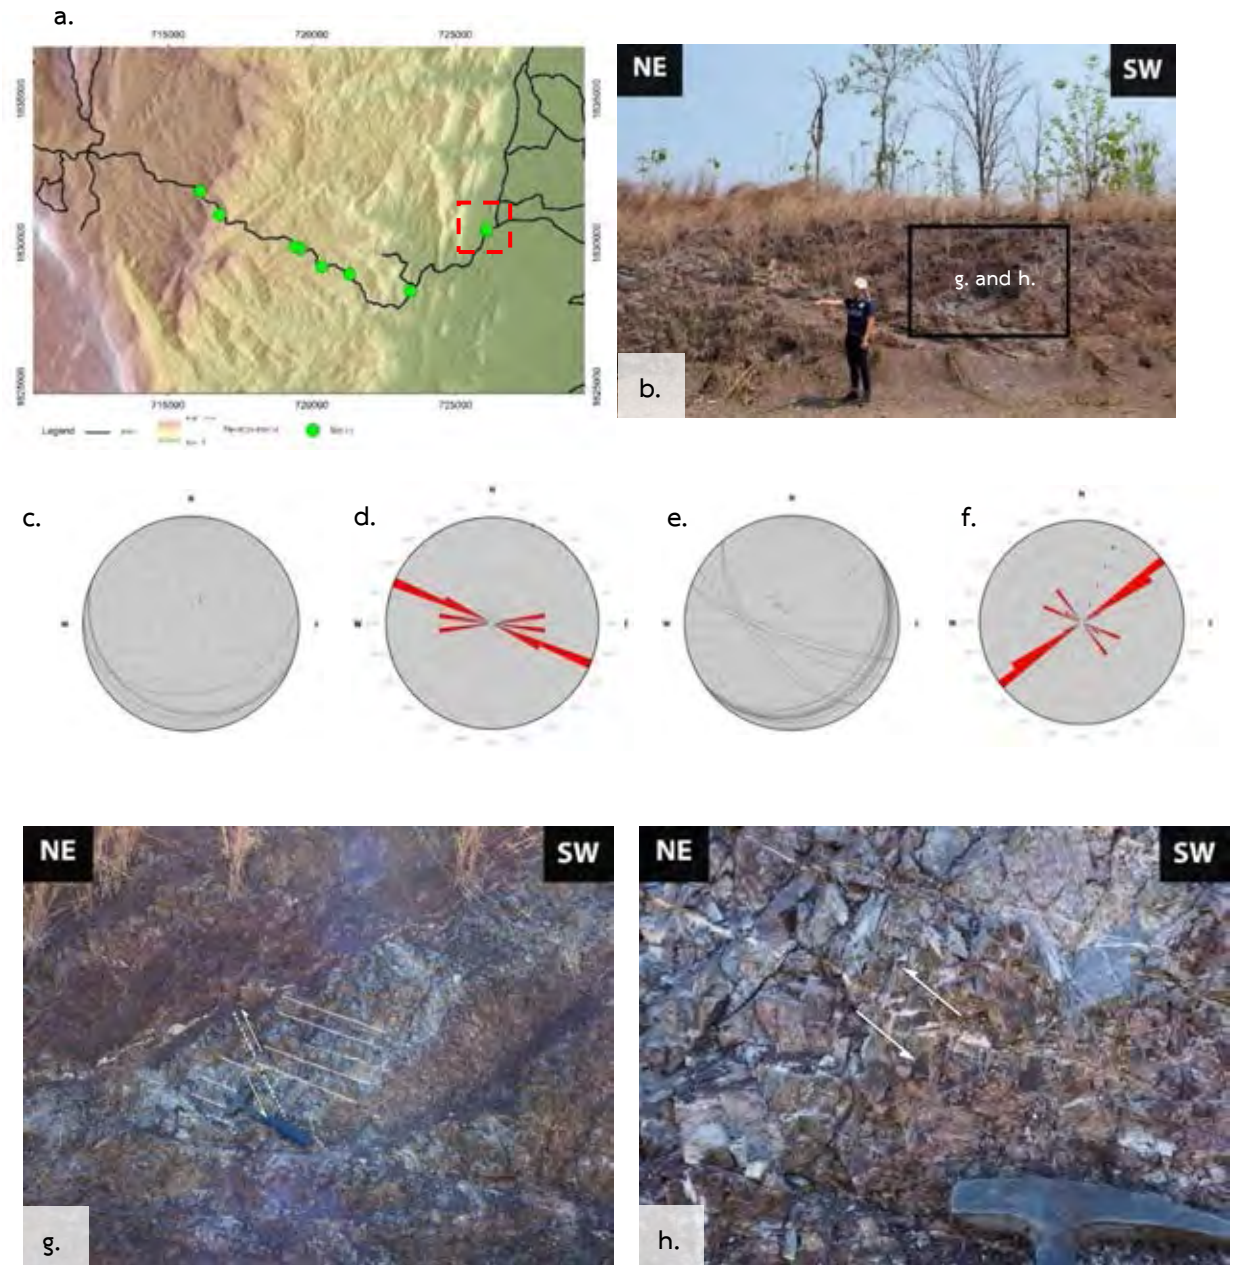

Fig 3.5 The outcrop station 1. (a) location in the dem map. (b) overview of outcrop in the station. (c) and (d) stereonet and rose diagram of fractures. (e) and (f) stereonet and rose diagram of joints. (g) and (f) joint sets and sense of movement.

Station2

Station 2 far from station 1 around 2 kilometers. Outcrop is 5 meters long and 3 meters high. Fractures in this station are North to South direction. There are 3 joint sets.

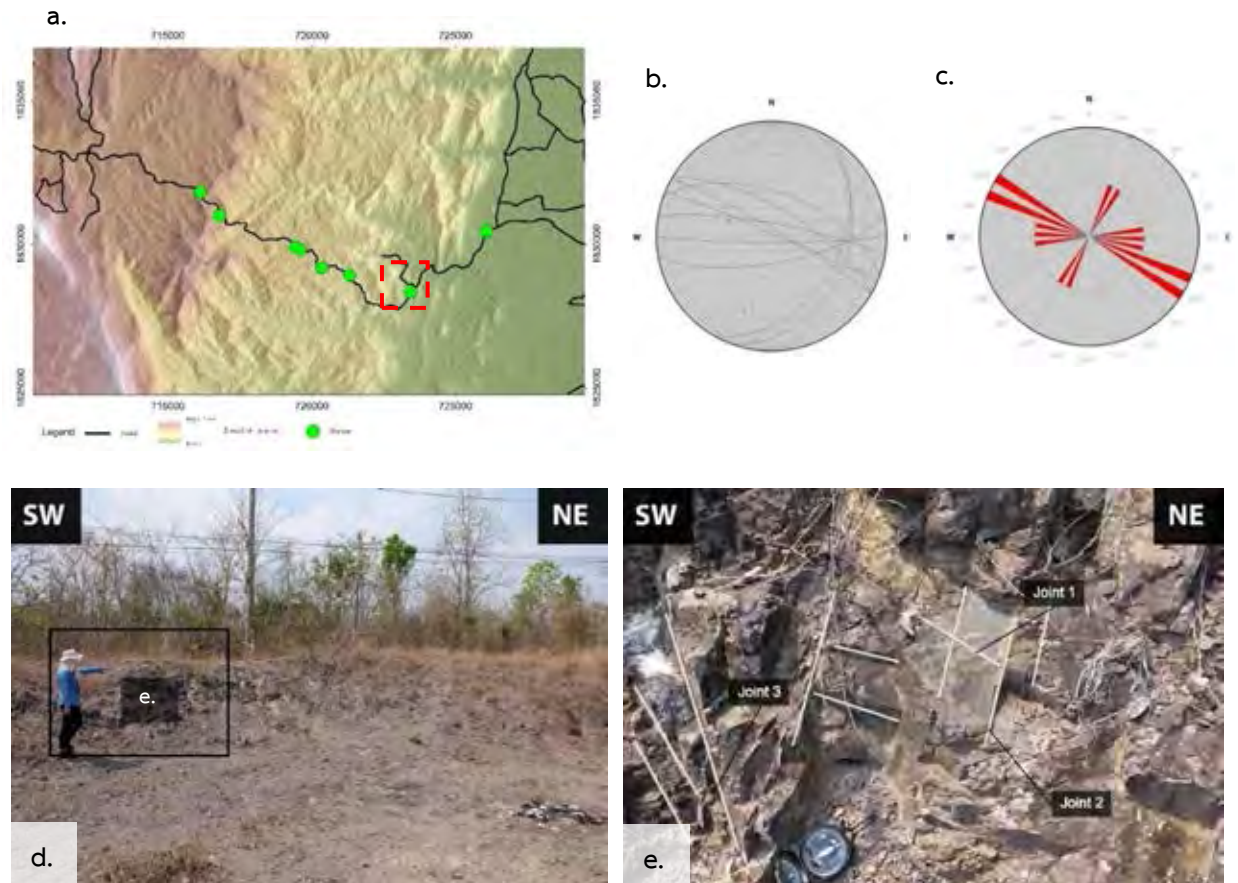

Fig 3.6 The outcrop station 2. (a) location in the dem map. (b) and (c) stereonet and rose diagram of joints. (d) overview of outcrop. (e) orientation of joint sets at outcrop.

Station 3

Station 3 far from station 2 around 1 kilometer. Outcrop is more than 50 meters long and 5 meters high. Fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, Normal fault. The Fault has dip angle around 60 to 80.

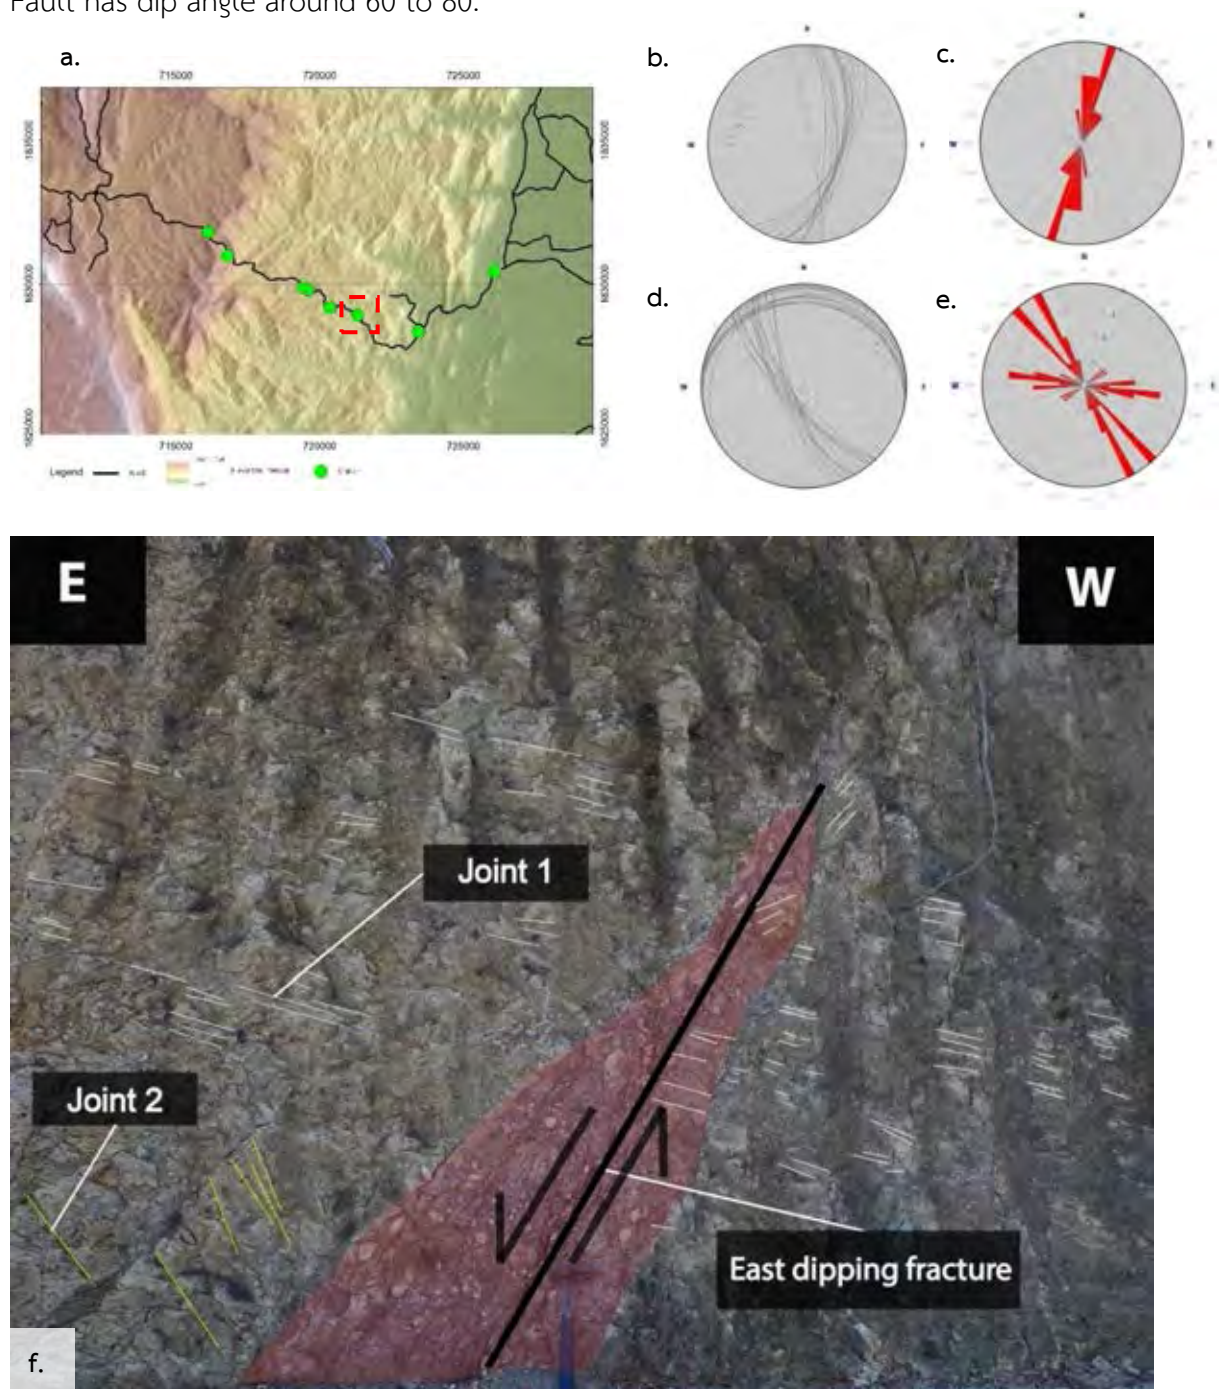

Fig 3.7 The outcrop station 3. (a) location in the dem map. (b) and (c) stereonet and rose diagram of fractures. (d) and (e) stereonet and rose diagram of joints. (f) orientation of joint sets, fracture and sense of movement.

Station 4

Station 4 far from station 3 around 500 meters. Outcrop is 20 meters long and 7 meters high. Fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, Normal fault and Thrust fault. The Faults have dip angle around 10 to 60.

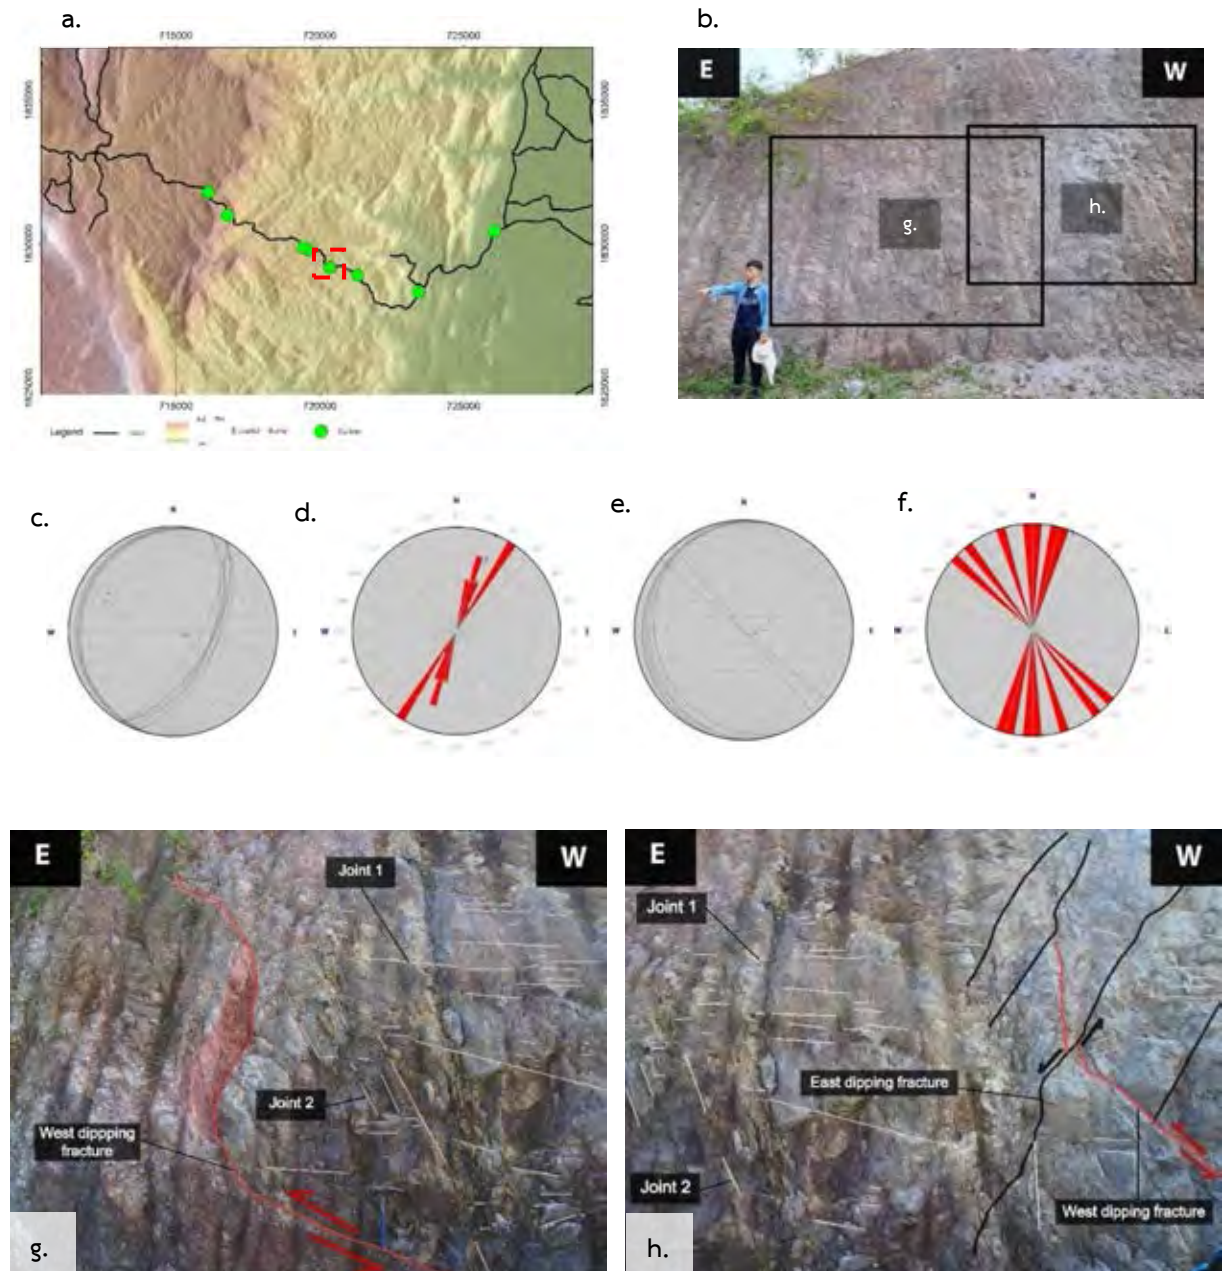

Fig 3.8 The outcrop station 4. (a) location in the dem map. (b) overview structural detail of outcrop. (c) and (d) stereonet and rose diagram of fractures. (e) and (f) stereonet and rose diagram of joints. (g) and (h) joint sets, east dipping fracture, west dipping fracture and sense of movement.

Station 5

Station 5 far from station 4 around 500 meters. Outcrop is more than 20 meters long and 10 meters high. Most of fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, Normal fault and Thrust fault. The Faults have dip angle around 10 to 85.

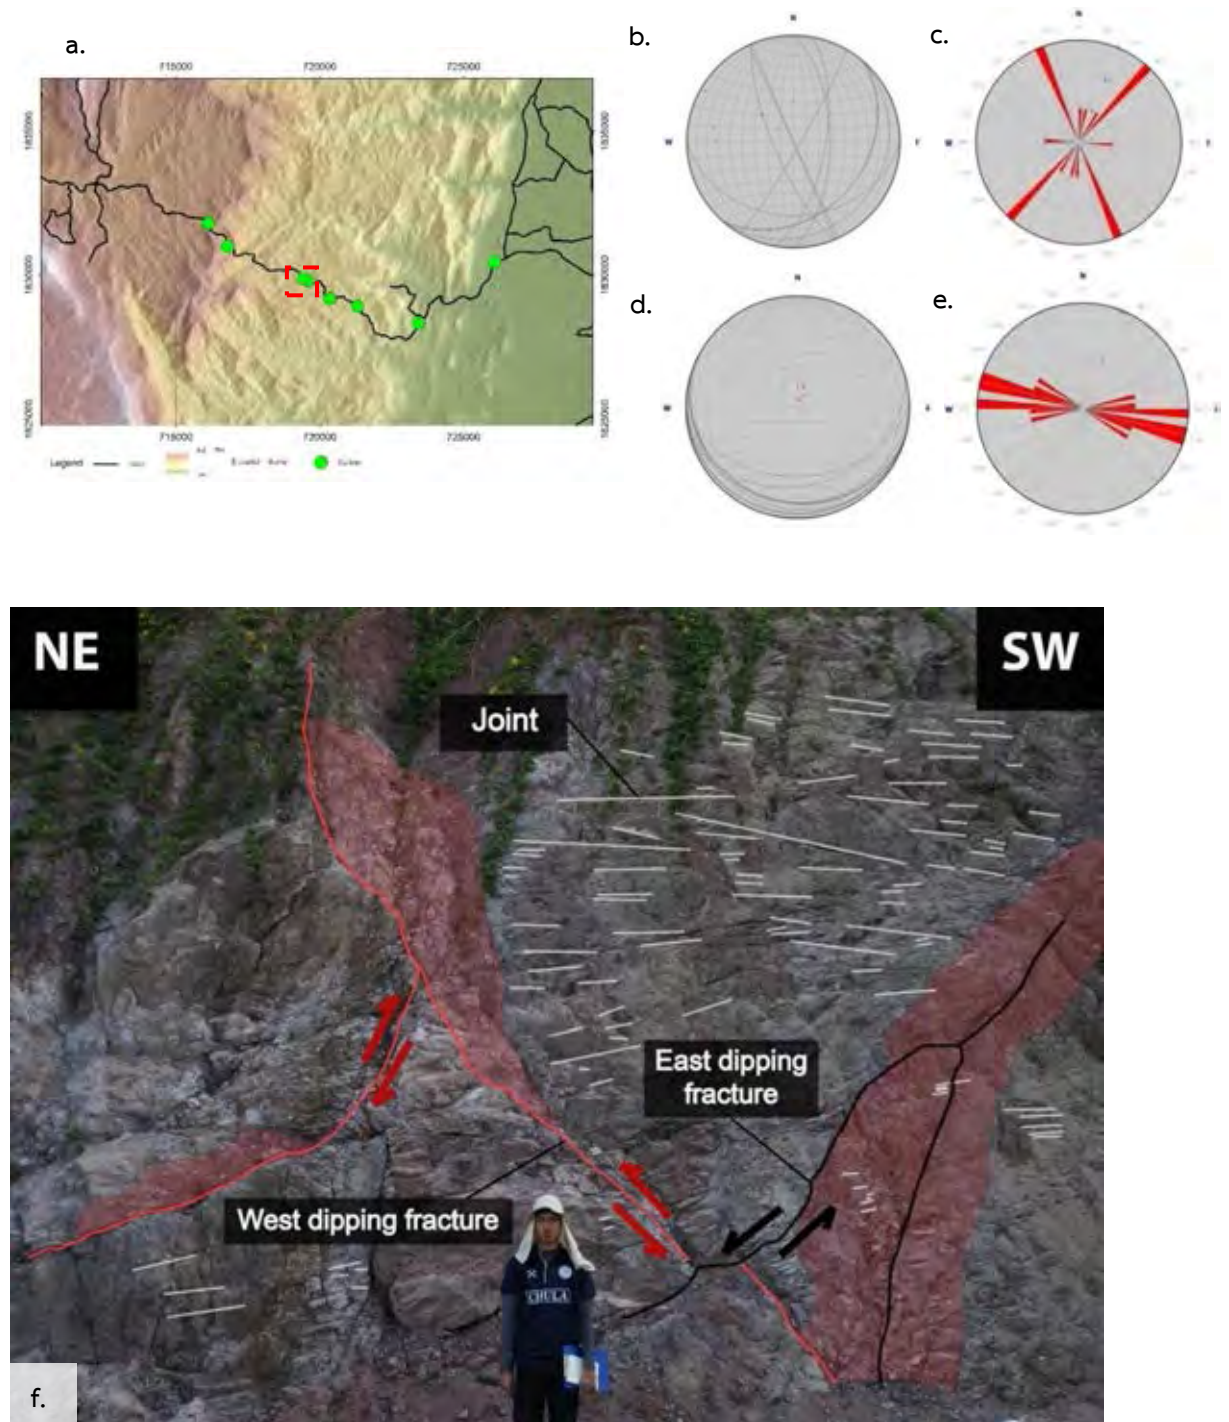

Fig 3.9 The outcrop station 5. (a) location in the dem map. (b) and (c) stereonet and rose diagram of fractures. (d) and (e) stereonet and rose diagram of joints. (f) orientation of joint sets, east dipping fracture, west dipping fracture and sense of movement.

Station 6

Station 6 is very close to station 5. It far from station 5 around 100 meters. Outcrop is more than 20 meters long and 10 meters high. Most of fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, fault. The Fault have dip angle around 65 to 85.

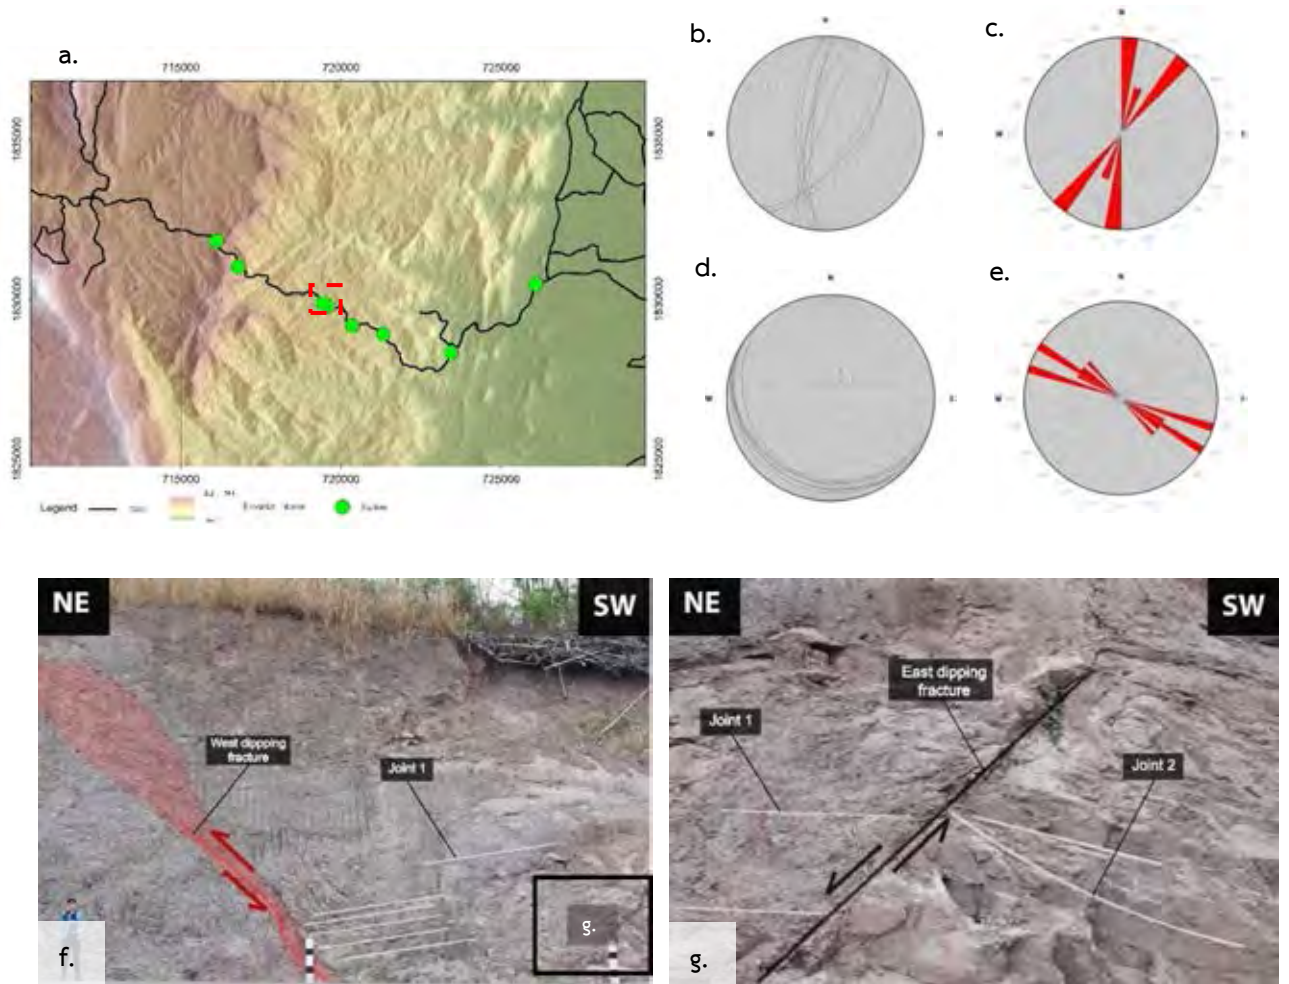

Fig 3.10 The outcrop station 6. (a) location in the dem map. (b) and (c) stereonet and rose diagram of fractures. (d) and (e) stereonet and rose diagram of joints. (f) orientation of joint sets, west dipping fracture and sense of movement. (g) joint sets, east dipping fracture and sense of movement.

Station 7

Station 7 far from station 6 around 2 kilometers. Outcrop is more than 10 meters long and 10 meters high. Fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, fault. The Faults have dip angle around 15 to 30.

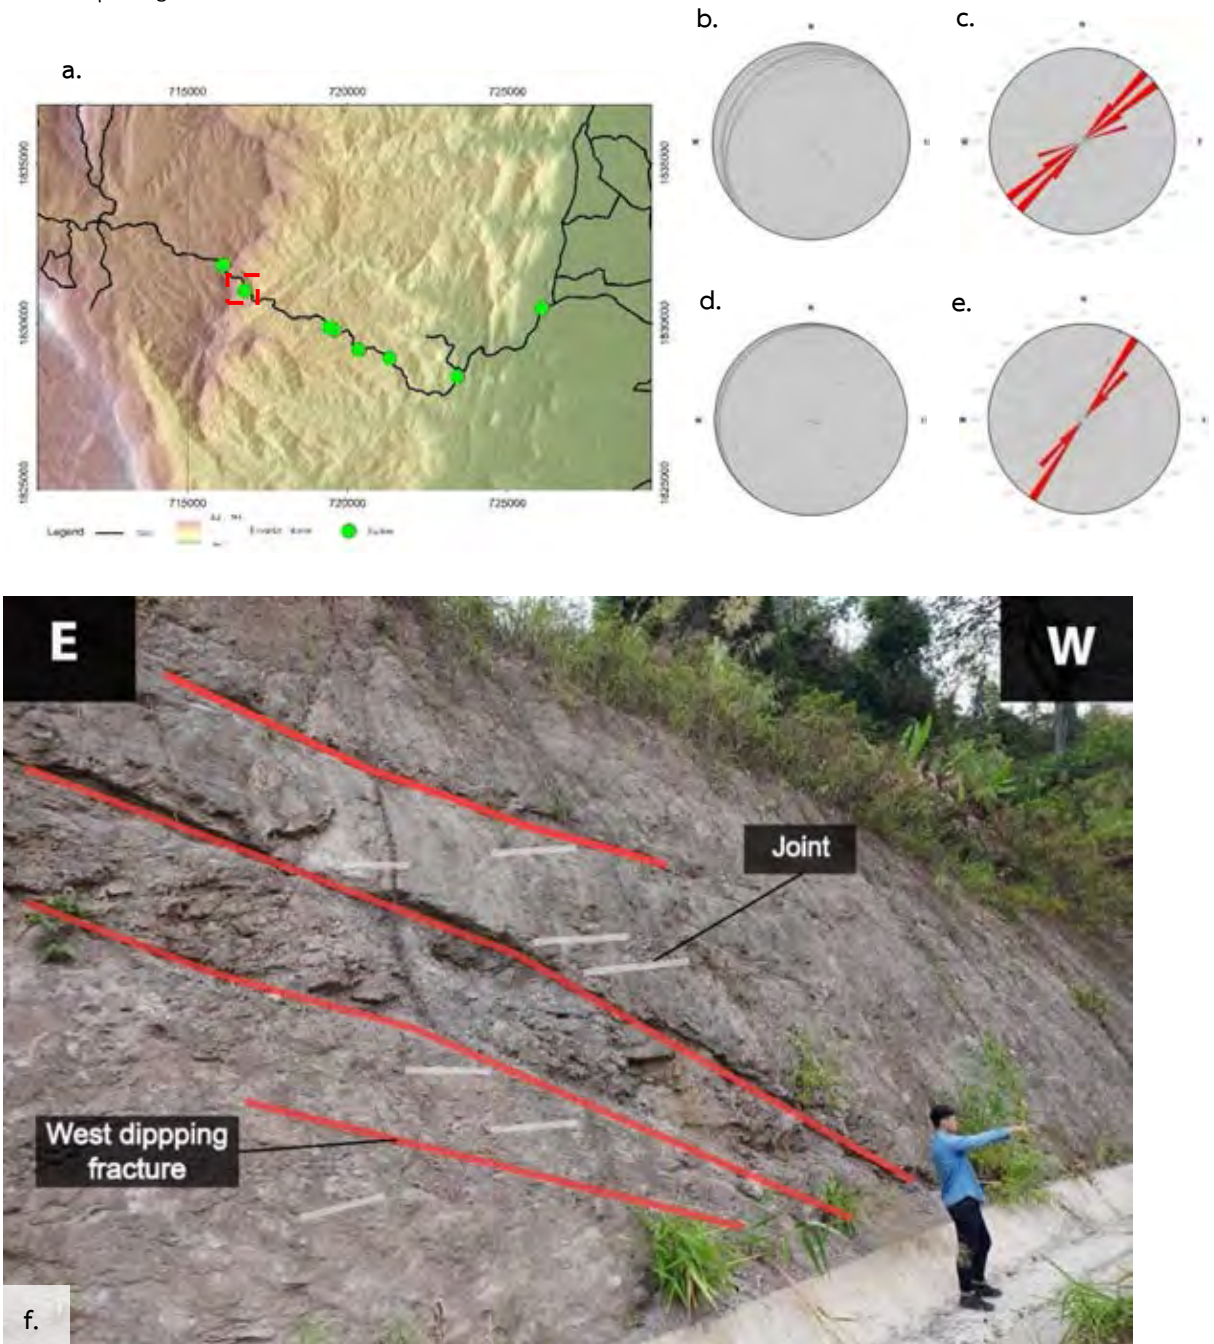

Fig 3.11 The outcrop station 7. (a) location in the dem map. (b) and (c) stereonet and rose diagram of fractures. (d) and (e) stereonet and rose diagram of joints. (f) orientation of joint sets and west dipping fracture.

Station 8

Station 8 is the last station. It far from station 7 around 1 kilometer. Outcrop is more than 20 meters long and 10 meters high. Fractures in this station are North to South direction. There are opening mode fracture, joint sets, and sliding mode fracture, fault. The Faults have dip angle around 10 to 30.

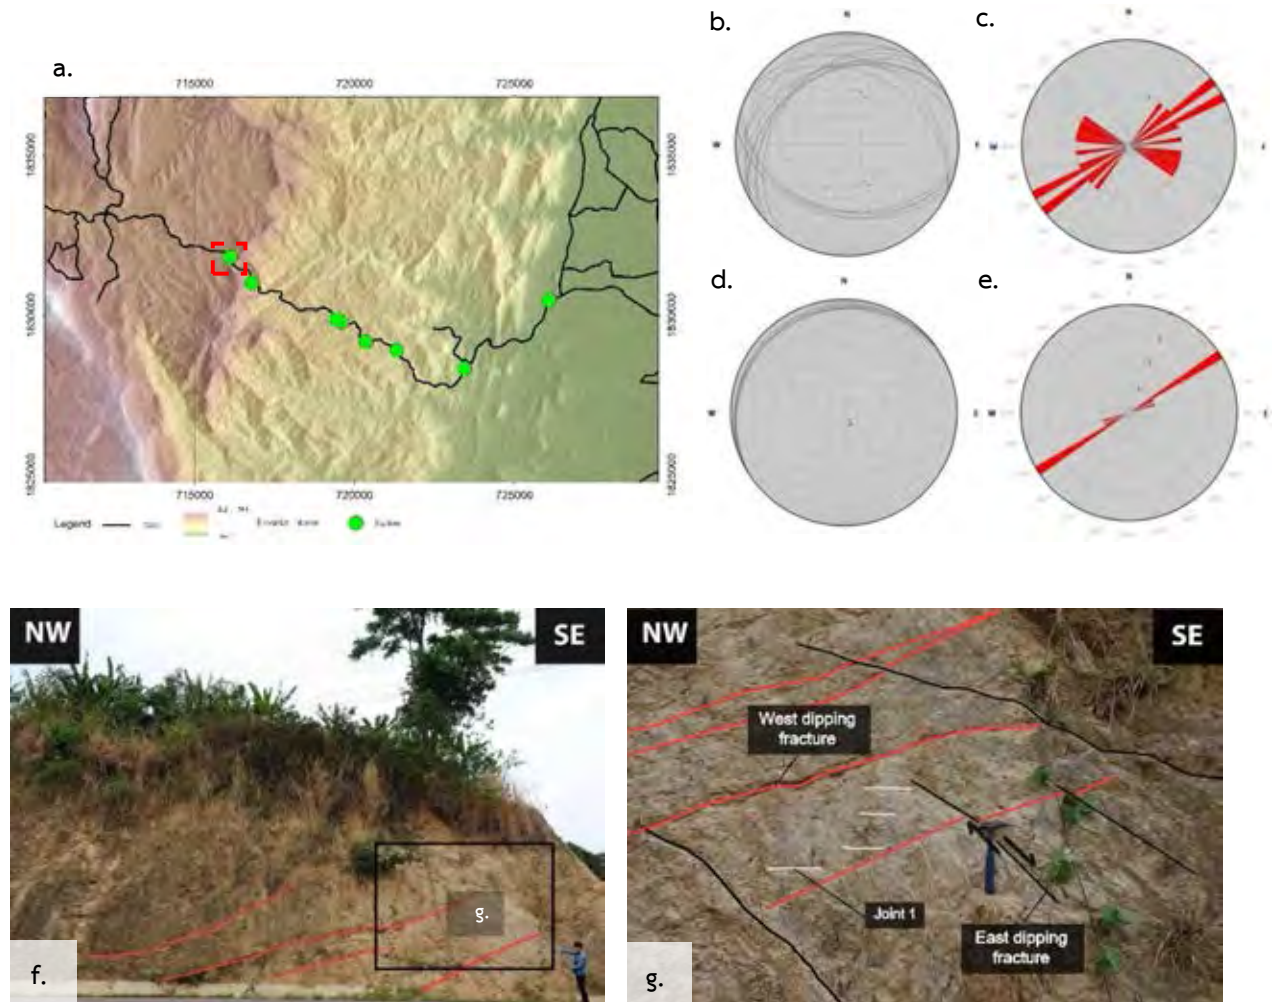

Fig 3.12 The outcrop station 8. (a) location in the dem map. (b) and (c) stereonet and rose diagram of fractures. (d) and (e) stereonet and rose diagram of joints. (f) overview structural detail of outcrop. (g) joint sets, west dipping fracture, east dipping fracture and sense of movement.

Chapter 4 Discussion

Chapter 4

From the 2 main results, Lithology and Structural geology, in chapter 3 can be explain in groups of fracture, structural style of fracture and evolution model of fracture along highway no.2196, Khao Kho district, Phetchabun province.

4.1 Groups of fracture

■ West dipping fractures

The west dipping fracture are lying on N-S and NW-SE direction and have dip angle from 5° to 45° . They show movement and fractures that related them. They found in station 1, 4, 5, 6, 7 and 8.

Fig 4.1 (a) stereonet data of west dipping fractures (40 data) in station station 1, 4, 5, 6, 7 and 8. (b) rose diagram of west dipping fractures in station 1, 4, 5, 6, 7 and 8. (c) stereonet data of joints (56 data) which is related west dipping fractures in station 1, 4, 5, 6, 7 and 8. (d) rose diagram of joints which is related thrust faults in station 1, 4, 5, 6, 7 and 8.

■ East dipping fractures

The East dipping fractures are lying on N-W direction and have dip angle from 60° to 75° . They found in station 3, 4 and 5. They show movement and fractures that related them. The fractures also have high dip angle (Fig 4.4c).

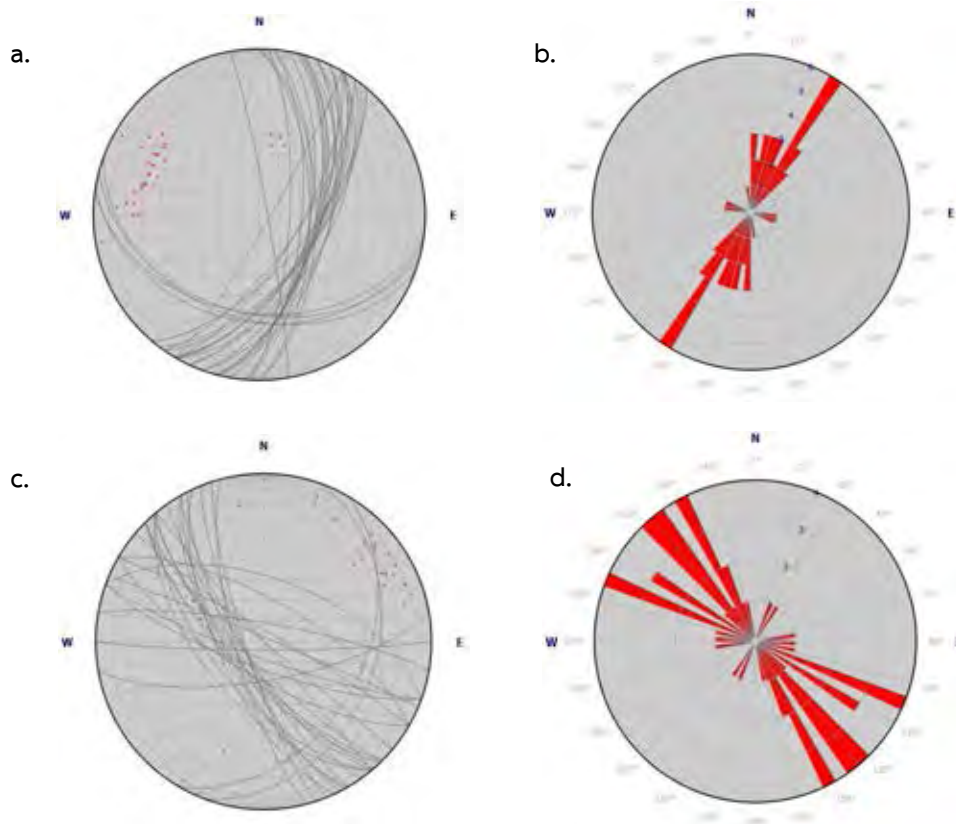

Fig 4.2 (a) stereonet of east dipping fractures (32 data) in station 3, 4 and 5. (b) rose diagram of east dipping fractures in station 3, 4 and 5. (c) stereonet of fractures (30 data) which are related east dipping fractures in station 3, 4 and 5. (d) rose diagram of fractures which is related east dipping fractures in station 3, 4 and 5.

4.2 Structural Style of fracture

The evidence of brittle deformation in the study area is 2 main groups fracture. **The first group** is West dipping fracture. They lie in Northeast-Southwest direction and have low dip angle (5-45 degree). Moreover, their movement is approximately from west to east. From the Anderson's classification (1950) suggested that there are reverse or thrust fault. But in the study area there were not actually reverse fault because they

had a curve plane. So, the first group is Reverse fault with curve plane also call “Listric reverse fault”. In addition, they have joints that also low angle. **The second group** is East dipping fracture. They lie in Northeast to Southwest direction. These fractures have very high dip angle. From the similarly Anderson’s classification suggested that there are normal faults. These 2 groups fracture have cross cutting relationship. The reverse faults have displacement from effect of normal faults. So, many evidences indicated that normal faults were younger than reverse faults.

Fig 4.3 Rock units, stations and cross-section line in the study area.

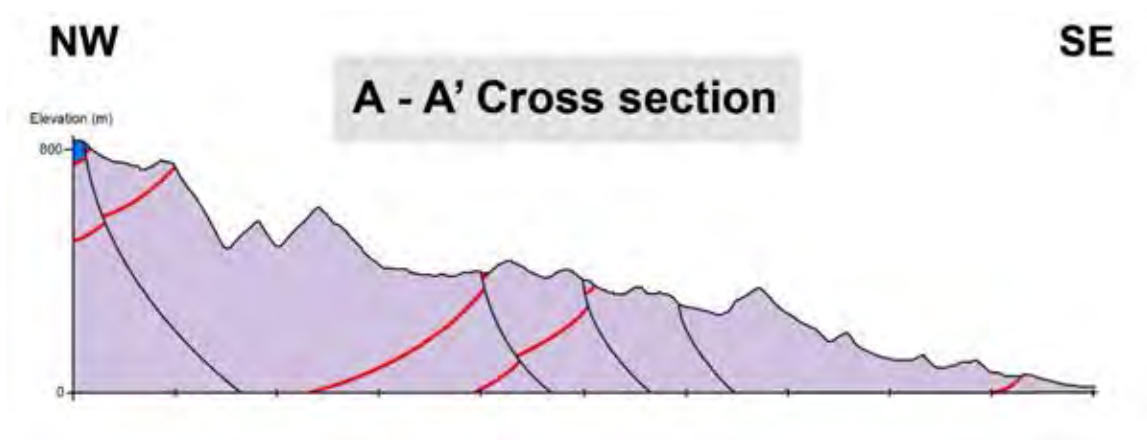

Fig 4.4 The A-A' cross-section profile

4.3 Evolution model of fracture

The evidence from all fractures and all analyzed data were take place in Huai Hin Lat formation that is in the Triassic. So, the relative age of fractures is 245 million years or earlier. They can be explained the evolution of them into 2 stages.

Stage I: Triassic

from Shan Thai sub-continent subducted into Indochina from west to east made compression force in E-W direction. This force made Indosinian orogeny. It also made first fracture group, which are reverse fault and low angle joint (opening mode fracture). These reverse faults have geometry like listric fault (Fig 25).

Stage II: Oligocene to Miocene

This period happened in Oligocene to Miocene. The effect from the strike-slip in this period ceased from the evidence of ramp-flat detachment in Pattani basin, one of Tertiary basins in Thailand. So, the Phetchabun basin and others Tertiary basins in Thailand was formed by intra-continental extension caused by subduction rollback under continental crust in the beginning of Oligocene. Moreover, these tension forces created the normal faults in the study area (Fig 26).

Stage I: Triassic

Chapter 5 Conclusion

Chapter 5

Conclusion

From the result in the field exploration and the analyzed data which is showed into rose diagram and stereonet and discussion about structural style and evolution of fractures along the highway no.2196, Kho-Kho district, Phetchabun province can be summarized from these following.

- The rocks in study area are suggested to be Huai Hin Lat formation in the geological map. It is grey to black tuff with sub-vertical bedding and can be correlated to andesitic tuffs of Jungyusuk & Khositantont (1992).
- Fractures in the study area can be divided into 2 groups, normal faults and reverse faults. The Normal faults have high dip angle, dipping to the east and have splay fracture. Reverse faults have low dip angle, dipping to the west and have related joints which also have low angle.
- The Evolution of fractures can be separated into 2 stages as follows;
 - Stage I: Triassic (E-W compression) created the Loei Fold Belt, reverse faults and low dip angle joints.
 - Stage II: Oligocene to Miocene (E-W extension) created Tertiary basin in Thailand and normal faults.
