

## CHAPTER IV

### RESULTS AND DISCUSSION

#### 1. In Vitro Studies

The concentrations of roxithromycin in the tablet were determined according to the modified method using high performance liquid chromatography from that of Oliveira, Bergold, and Schanpoval (1996). Typical chromatograms of internal standard (clarithromycin) and roxithromycin are shown in Figure 2. The retention times of internal standard and roxithromycin were 9.55 and 11.63 minutes, respectively. The method was validated for the within-run and between-run precisions. The percent coefficient of variation (%C.V.) in the within-run and between-run precisions were 0.63-2.48% and 0.84-7.51% as shown in Tables 2 and 3, respectively. The accuracy was evaluated by calculating the percent recovery of roxithromycin. Results as shown in Table 4, the percent recovery of roxithromycin was in the range of 99.34 to 100.39%.

All three commercial brands of 150 mg roxithromycin tablets were first tested for uniformity of dosage units and content of active ingredient. Each of these three brands met the United States Pharmacopoeia 1995 (USP XXIII) for content uniformity within the range of 85.0-115.0% of the labeled claim and the percent coefficient of variation (%C.V.) was less than 6.0%. All products were assayed for content of active ingredient and found that each brand was within the limits of 90.0-110.0 percent labeled amount. The percent labeled amount (%L.A.) of the all products were closed to upper limits of the USP XXIII requirements. The reason might be the manufacturer would like to keep longer of the shelf-life and antibacterial activity of drug. The disintegration testing of all products revealed that all products were able to disintegrate within 30 minutes. Brand A showed fastest disintegration followed by brands B and C, respectively. Results of all test were summarized in Table 5.

The dissolution testing of roxithromycin tablets was a crucial factor for systemic drug availability because the drug was practically insoluble in water. Since

the method of dissolution testing for roxithromycin was not described elsewhere, the new procedure was tried out. The United States Pharmacopoeia paddle method using phosphate buffer pH  $7.4 \pm 0.1$ , 900 mL was found to be the most reasonable mean.

Table 6 and Figure 3 illustrated the dissolution profiles at various sampling times of all products of roxithromycin tablets. The mean percent dissolved of roxithromycin from all brands were greater than 80 percent at 45 minutes. The dissolution rate constants ( $K_d$ ) were calculated from the slope of the first order plot between the amount of undissolved roxithromycin ( $B_\alpha - B_t$ ) versus time in semi-logarithmic scale and results were reported in Table 7. The rank order of these dissolution rate constants for all brands were brands  $A > B > C$ . All sampling times, the mean percent dissolved of roxithromycin from brand A was higher than brands B and C (Table 6 and Figure 3), it might be due to the difference in formulation and manufacturing process as well as the contribution of disintegration results as seen by the two tests were highly correlated. Statistical comparison, as presented in Tables 8 and 9, indicated that with respect to brand A, dissolution rate constant of brand B was not statistically significant difference ( $p > 0.05$ ) while the value of brand C was statistically lower ( $p < 0.05$ ).

## 2. In Vivo Studies

### 2.1 Analysis of Roxithromycin in Plasma

Plasma Roxithromycin concentrations were analyzed by microbiological agar diffusion assay. In this study, the procedure of Campa et al. (1990) and Barry (1986) was modified for analyzing roxithromycin concentrations in plasma samples. The method involved precipitation of proteins from plasma and the drug was extracted using absolute ethanol.

The assay method was validated by determining the within-run and between-run precisions as well as accuracy. The percent coefficient of variation (%C.V.) in the within-run and between-run precisions were 0.22-1.63 % and 0.76-2.98 % as shown in Tables 10 and 11, respectively. The percent recovery for accuracy

$$1. r^2 = 0.9990, \quad \log y = 0.1306x - 2.3604$$

: x = Inhibition zone diameter, y = plasma roxithromycin concentration

2. Inversely estimated concentration

$$= \text{antilog} \{ (\text{Inhibition zone diameter}) \times 0.1306 - 2.3604 \}$$

$$3. \% \text{ Recovery} = \frac{\text{Inversely estimated concentration}}{\text{Known Concentration}} \times 100$$

$$4. \% \text{ C.V.} = \frac{\text{S.D.}}{\text{Mean}} \times 100$$

was 99.86 as report in Table 12. The calibration curve of the inhibition zone diameters versus the logarithm of plasma concentration of roxithromycin was linear up to 10 µg/mL (Appendix B, Table 32 and Figure 19).

## 2.2 Plasma Roxithromycin Concentrations

The plasma concentration of roxithromycin at each sampling time interval ranging from 0 to 24 hours after oral administration of 150 mg roxithromycin tablet of brands A,B and C are shown in Tables 13 to 15, respectively. Individual plasma roxithromycin concentration-time profile for each of twelve subjects were shown graphically from Figures 4 to 15. Comparison of the mean plasma roxithromycin concentration profile of each brand from twelve subjects were illustrated in Figure 16.

The plasma roxithromycin concentration in some subject of all three brands showed irregular absorption phase as seen by occurring two or three peak concentrations. This might be explained that roxithromycin has enterohepatic cycling affecting the reabsorption of drug which was repeated until it was totally eliminated. The mean plasma roxithromycin concentration of brands A and B showed more than one peak concentration while brand C did not. This might be due to the intersubject variations.

## 3. Bioavailability Evaluation

The pharmacokinetic parameters,  $C_{max}$ ,  $t_{max}$  and AUC are used to characterize the bioavailability of pharmaceutical formulation after administration. The parameters,  $C_{max}$  and  $t_{max}$  represented the rate of drug reaching the systemic circulation while the AUC value indicated the extent of absorbed drug entering the systemic circulation. They are derived from plasma drug concentration-time data. In the bioequivalence study, drug products that are pharmaceutically equivalent are accepted to be bioequivalent if no statistically significant difference in the rate and the extent of drug absorption can be observed (Shargel and Yu, 1980) as well as the ratios of individual parameter of the test products relatively to the reference product were

contained within 80-125% of 90% confidence interval (The United States Pharmacopoeia XXIII).

The relevant pharmacokinetic parameters obtained for bioavailability comparison are as follows :

### 3.1 Peak Plasma Concentration ( $C_{max}$ )

Previous reports indicated that the mean peak plasma concentration achieved following oral administration of 150 mg roxithromycin was about 6.6-7.9  $\mu\text{g/mL}$  (Kees et al., 1988). In this study, the mean peak plasma roxithromycin concentration for brands A, B and C were  $6.35\pm 0.52$ ,  $6.40\pm 0.33$  and  $6.26\pm 0.49$   $\mu\text{g/mL}$ , respectively, as seen in Table 16. The rank orders of these values were  $B > A > C$ . Table 17 showed that there were no statistically significant difference ( $p > 0.05$ ) between all three brands, even though the intersubject variations was rather large ( $p < 0.05$ ). The ratio of  $C_{max}$  of brands B and C relatively to brand A were 96-109 and 92-111%, respectively.

The plasma profiles obtained showed more than one peak thus the  $C_{max}$  was selected from the highest peak plasma concentration. These observed  $C_{max}$  were less than those of the previous studies. The reasons might be the difference of assay method as well as race and biological behavior of subjects. In Thais, the drug may be metabolized rapidly than foreigner.

The  $C_{max}$  of brand C was slightly lower than those of the two brands, these might be the drug was less absorbed than others.

### 3.2 Time to Peak Plasma Concentration ( $t_{max}$ )

The time to peak plasma roxithromycin concentration of each individual was presented in Table 18. The average times were  $1.46\pm 0.18$ ,  $1.42\pm 0.14$  and  $1.46\pm 0.16$  hours for brands A, B and C, respectively. The rank order of these values were  $B < A = C$ . The  $t_{max}$  of brand B was lower than those of brands A and C, indicated that the drug of brand B was absorbed into the systemic circulation rapidly than others.

**Table 18** Time to Peak Plasma Concentration ( $t_{\max}$ ) of Roxithromycin Following Oral Administration of Three Brands of 150 mg Roxithromycin Tablets

Subject No.	$t_{\max}$ (hr)		
	Brand A	Brand B	Brand C
1	1.50	1.00	1.00
2	1.50	1.00	0.50
3	1.50	1.00	2.00
4	1.00	2.50	1.50
5	1.00	1.00	1.50
6	0.50	2.00	1.50
7	2.00	1.50	1.50
8	1.00	1.00	1.50
9	1.00	1.50	1.00
10	2.50	1.50	2.00
11	1.50	1.50	2.50
12	2.50	1.50	1.00
Mean	1.46	1.42	1.46
S.E.M.	0.18	0.14	0.16

There were no statistically significant difference ( $p>0.05$ ) among these values of all three brands (Table 19). The ratio of  $t_{max}$  of brands B and C relatively to brand A were 85-120 and 82-118%, respectively. The time to peak plasma roxithromycin concentration in this study agreed well with those found by other reports, which ranging from 1.5-1.93 hours (Young et al., 1989). The study also indicated that dissolution process of the drug was not the rate limiting step of drug absorption. As seen in Table 9, brand C had  $K_d$  statistically lower than others, it still produced similar the time to peak value like any other brands did.

### 3.3 Area Under the Plasma versus Time Curve (AUC)

The mean AUC from individual plasma of all brands were  $53.39\pm 4.58$ ,  $52.89\pm 4.64$  and  $53.18\pm 4.32$   $\mu\text{g hr/mL}$  for brands A, B and C, respectively, as shown in Table 20. The rank order of these values were  $A > C > B$ . According to Table 21, there were no statistically significant difference ( $p>0.05$ ) between all three brands. The ratio of AUC of brands B and C relatively to brand A were 88-113 and 87-114%, respectively.

For the antibacterial drug such as roxithromycin, the AUC reflected the total amount of active drug that reached to the systemic circulation and produced clinical efficacy. The values of AUC in this study were lower than those presented by Young et al., 1989 (72.6-81.0  $\mu\text{g hr/mL}$ ). The difference might be caused by the difference of assay method as well as race and biological behavior of subjects as the same results as the  $C_{max}$ .

AUC of brand A was slightly greater than those of two brands, although it had lowest of %L.A.. These results indicated that AUC was not related to %L.A. and  $C_{max}$ .

The principal pharmacokinetic parameters of roxithromycin following oral administration of three brands were summarized in Table 22. The 90% confidence interval based on ratio of bioavailability parameters ( $C_{max}$ ,  $t_{max}$  and AUC) were fully

\* 90% Confidence interval of parameter ratio of tested product and innovator's product

contained within a practical bioequivalence range (80-125%). According to guideline for bioequivalence in USP XXIII, it could be concluded that brands B and C were bioequivalent to the innovator's product (brand A) in terms of both the rate ( $C_{max}$  and  $t_{max}$ ) and the extent of the drug absorption (AUC) into systemic circulation.

#### 4. Pharmacokinetics of Roxithromycin Tablets

The pharmacokinetics of roxithromycin following oral administration of 150 mg roxithromycin tablet in healthy Thai male volunteers, which the result revealed that roxithromycin had biphasic elimination manner. The elimination phase of the concentration-time profile showed a fast declining initial phase and a slowly elimination phase thereafter. It could be explained by a two compartment model with first-order absorption and first-order elimination. This finding agreed with the study of Campa et al.,1990.

##### 4.1 Absorption Rate Constant ( $K_a$ )

The average absorption rate constants for brands A, B and C were  $0.58 \pm 0.10$ ,  $0.66 \pm 0.07$  and  $0.54 \pm 0.08$   $hr^{-1}$ , respectively as shown in Table 23. The rank order of these values were brands  $B > A > C$ . Statistical analysis results in Table 24 indicated that there were no significant difference ( $p > 0.05$ ) among these values of all brands. Absorption of drug appeared to be independent of drug dissolution. This was seen by, even though brand A showed higher dissolution rate than brand B did, the rate of drug absorption from brand B appeared to be greater.

##### 4.2 Elimination Rate Constant ( $K_e$ )

The average elimination rate constant obtained from individual plasma data of brands A, B and C were  $0.10 \pm 0.005$ ,  $0.11 \pm 0.004$  and  $0.10 \pm 0.005$   $hr^{-1}$ , respectively (Table 25). There were no statistical difference among these values of all three brands ( $p > 0.05$ ) as shown in Table 26, indicating that the drug was eliminated from the body with the same rate although the drug showed intersubject variations.

### 4.3 Elimination half-life ( $t_{1/2}$ )

The mean elimination half-life of roxithromycin determined for brands A, B and C were  $7.01 \pm 0.38$ ,  $6.60 \pm 0.23$  and  $6.78 \pm 0.31$  hr, respectively (Table 27). Statistical analysis showed no significant difference among these values (Table 28). The values disagreed with the results found by other investigators ranging from 8.4-15.5 hours (Tremblay et al.,1988). This might be due to the metabolism of drug in Thais were rapidly than foreigner.

The pharmacokinetic parameters of roxithromycin from twelve subjects following oral administration of three brands were summarized in Table 29.

Table 27 Elimination Half-life ( $t_{1/2}$ ) of Roxithromycin Following Oral Administration of Three Brands of 150 mg Roxithromycin Tablets
