KEYWORD: Nickel phyllosilicate, furfural, furfuryl alcohol, CO₂ methanation

Sasithorn Kuhaudomlap : Preparation of nickel phyllosilicate catalysts by one-step modified spherical silica synthesis in carbon dioxide hydrogenation and selective hydrogenation of furfural to furfuryl alcohol. Advisor: Prof. JOONGJAI PANPRANOT, Ph.D.

Spherical silica derived nickel phyllosilicate catalysts were prepared via a one-step modified spherical silica synthesis under room temperature. For 10wt% Ni loading, the loading sequence of Ni and Si sources during spherical silica synthesis was found to affect the characteristics and catalytic properties in CO₂ methanation. The stronger interaction between Ni and silica in the form of nickel phyllosilicate revealed the better catalytic performances than the impregnation method. The highest CO₂ methanation activity and methane selectivity were obtained over the catalyst prepared by alternate loading between Ni and Si (Ni_Alt_Si) due to high electron density of nickel on the surface, high metal dispersion, and high CO₂ adsorption ability. Furthermore, one step synthesis by alternate addition of Ni and Si precursor (Ni_Si) with different Ni loadings in the range of 2-30 wt% were evaluated in the selective hydrogenation of furfural to furfuryl alcohol. The unique properties of the remaining nickel phyllosilicate after reduction could act as a good support for metallic nickel, yielding high dispersion of small nickel particles and stable catalytic performances for multiple recycle runs. Furfural conversion over the Ni_PS catalysts increased monotonically with increasing Ni loading without FA selectivity drop. It is suggested that the presence of both metallic Ni⁰ and Ni_{phyllosilicate} also produced a synergistic promotional effect for FA formation.

ACKNOWLEDGEMENTS

I am deeply grateful to my thesis advisor, Prof. Dr. Joongjai Panpranot for her invaluable help and constant encouragement throughout the course of this research. I am most grateful for teaching and advice. I would not have achieved this far and this thesis would not have been completed without all the support that I have always received from her.

I also would like to grateful to Assoc. Prof. Dr. Okorn Mekasuwandumrong as a chairman, Prof. Dr. Anongnat Somwangthanoj, Dr. Chutimon Satirapipathkul and Asst. Prof. Dr. Suphot Phatanasri as a member of the thesis committee for your brilliant comments and suggestions. Moreover, I also want to thank you for letting my defense be an enjoyable moment

I would grateful to thank to Prof. Christopher W. Jones for his suggestion and guidance about my research as well as all his help during my visiting at Georgia Tech.

I most gratefully acknowledge my parent and my friends for all their support throughout the period of this research.

Finally, I would like to thank the financial support for this work under the Royal Golden Jubilee (RGJ) – Ph.D. scholarship from Thailand Research Fund and Chulalongkorn University. In addition, I am would like to thank the financial support from RGJ Ph.D. scholarship and the William R. McLain Chair at Georgia Tech for work in Atlanta.

CHAPTER I

INTRODUCTION

1.1 Statement and significance of the problems

Recent research on catalyst development not only focuses on their excellent catalytic performances but also on the environmental friendly properties, low cost, good stability, and recyclability. Silica supported nickel catalysts (Ni/SiO_2) are versatile catalysts with interesting properties due to their low cost, high specific surface area, controllable morphology/adjustable pore structures, and high availability and easy functionalization [1-3]. In addition, silica support can be prepared with environmentally friendly silicon source by using biomass raw material such as distiller' grains [4], rice husk [5], *equisetum fluviatile* [6]. Thus, Ni/SiO_2 catalysts are widely used in various catalytic reactions in both gas phase and liquid phase reaction. However, Ni species obtained from the conventional impregnation method usually suffer from sintering/agglomeration of nickel particles at high temperature during the pretreatment/reaction process or leaching of nickel species in liquid phase reaction because of its relatively weak interaction between nickel species and silica supports. These issues have become major problems for conventional silica supported nickel catalysts, which usually cause deactivation of catalysts, low surface availability, large amount of waste resources, loss of catalytic activity, and poor stability/recyclability. Many efficient strategies have been applied to develop Ni/SiO_2 catalysts including the addition of various promoters such as La_2O_3 [7] and V_2O_5 [6], the improvement of the porous structure and morphology of support/catalysts [8], the modification of preparation method [9, 10], the formation perovskite and hydrotalcite structures [11, 12], and the formation of unique structure/compound with a strong metal-support interaction [13]. However, these methods have some limitations such as high cost, loss of surface availability, low loading, complicate preparation process, required multiple steps and unique instruments for preparation. Therefore, it is a great challenge to

design and synthesize high performance Ni/SiO₂ catalysts with a simple preparation method, low-cost process, high nickel dispersion, unique structure, a strong metal-support interaction for adsorption more active sites, as well as good anti-sintering and stability property for large scale reaction.

Nickel phyllosilicate is a stable material with a strong metal-support interaction due to unique layer structure which consists of tetrahedral layers of SiO₄ (Si-O-Si) and octahedral layers of Ni (II) (Ni coordinated to oxygen atoms or hydroxyl groups, Si-O-Ni-O(OH))[4, 14]. These nickel species offer outstanding properties such as strong metal-support interaction, small metal domain size and high dispersion of active metal species, high specific surface area, rich porous structures, excellent adsorption properties, high thermal stability, tunable pore structure and morphology, adjustable component and synthesizing parameter, very cheap raw material and simple preparation procedures[15]. The reduction treatment of nickel phyllosilicate in H₂ can provide fine nickel particles size with strong interaction between nickel and silica material at high nickel content and high metal dispersion[16]. The complete reduction of nickel phyllosilicate to nickel metal is difficult and above 700°C[14]. Interestingly, it has been reported that the remaining of nickel phyllosilicate layer after reduction process could act as a good/stable support for metallic nickel, which resulted in the highly dispersed nickel particles with small size of homogeneous nickel particle, preventing the sintering and enhancing the stability[17]. Due to the unique structure and special properties, Ni/SiO₂ catalysts derived from nickel phyllosilicate have received considerable attention in recent catalysis research and could be an efficient strategy to address the sintering and leaching problem, as well as good stability for a Ni/SiO₂ catalysts.

Generally, the importance factors for the formation of nickel phyllosilicate are a nickel precursor and a silica material or monomer silica source and a reaction

environment (an alkaline or acidic condition) [18]. Nickel phyllosilicates are commonly synthesized via various methods including hydrothermal methods [1, 5, 14, 19], the ammonia evaporation method [20-22], deposition-precipitation methods [23, 24] and sol-gel method [25] through the reaction between nickel precursor and silica materials. Among which, the hydrothermal method has been widely employed for preparation of nickel phyllosilicate catalysts due to high crystallinity and high nickel content (depend on the hydrothermal temperature), handy experimental operation, environmentally friendly, and uniform dispersed of nickel phyllosilicate [4]. However, conventional hydrothermal reaction is carried out in an autoclave under harsh hydrothermal conditions at high temperature ($>180\text{ }^{\circ}\text{C}$) with long reaction time (> 24 h), resulting in the loss of surface silanol group, limited nickel loading (even though there are excess nickel and silica amount) [7, 19, 26, 27], and small amount of nickel phyllosilicate and large particles being formed at relatively low hydrothermal temperatures (e.g. 120 and $160\text{ }^{\circ}\text{C}$) [16]. Thus, how to improve and synthesize Ni phyllosilicates with high nickel contents under mild conditions that can remain the superiority properties of nickel phyllosilicate is a great challenge. Chen et al. [4] synthesized nickel phyllosilicate via the hydrothermal method assisted by NH_4F and urea, which optimal nickel phyllosilicate (N/D-120-12) exhibited high catalytic performance for CO_2 methanation and excellent anti-sintering property. They reported that ammonium fluoride and urea can be efficient accelerator of the formation of H_4SiO_4 and $\text{Ni}(\text{OH})_2$, respectively which is essential intermediates for the formation of nickel phyllosilicate. Li et al. [1] found that nickel phyllosilicate could be formed under mild hydrothermal conditions at $100\text{ }^{\circ}\text{C}$ for 12 h by double accelerators of ammonium fluoride and urea which has similar morphology and nickel content with conventional hydrothermal method at $220\text{ }^{\circ}\text{C}$ for 48 h. Although, these modified hydrothermal method can improve hydrothermal condition, there are still some limitation of

complicated operation procedure and too low hydrothermal conditions still provides low nickel content and small amount of nickel phyllosilicate formation [4].

Moreover, the preparation of nickel phyllosilicate usually consists of two major steps: step (1) silica material synthesis and step (2) nickel phyllosilicate formation via the reaction of silica material and nickel precursor. Two step synthesis offer an efficient catalyst; however, it consumes large amounts of the reagent and energy, complicate preparation process and requires long operation time. Thus, a simple one step strategy is in need and achieved extensive attention due to their advantages such as low cost, high efficiency and convenience, and elimination of the separation, drying and calcination process. One-pot synthesis of Ni phyllosilicates has recently been reported, for example, Chen et al. [26] prepared 3D-SBA-15 derived Ni phyllosilicate via a one-pot and two-pot hydrothermal methods at 180 °C. Compared with two-pot, one-pot synthesis exhibited small size nickel particles, high nickel phyllosilicate content, fine nickel particle size, monolithic appearance and showed high anti-sintering due to strong metal-support interaction derived from nickel phyllosilicate. In addition, it was found that hydrothermal conditions were significant factor for the formation of nickel phyllosilicate via one-pot synthesis, which sectional hydrothermal at 100 °C, 24 h and 180 °C, 24 h affected to the formation of nickel phyllosilicate in their work. Therefore, a simple one-step strategy has attracted great interest to synthesize nickel phyllosilicate and modified/applied with the spherical silica synthesis under mild conditions. The spherical silica synthesis has a facial preparation process with tunable components in a wide range, which nickel species can uniformly dispersed during spherical silica synthesis with one-step method.

The Ni phyllosilicates show good performances in a number of reactions including CO₂ and CO methanation [16], hydrogenation of levulinic acid to γ -valerolactone [28], xylose hydrogenation to xylitol [24], hydrogenation of maleic

anhydride [15], hydrogenation of polycyclic aromatic hydrocarbons [29], and carbon dioxide reforming of methane [30]. To our knowledge, the nickel phyllosilicate derived catalysts have been widely explored in various gas phase reactions, there are few research focused on the catalytic properties of nickel phyllosilicate in liquid phase reaction, especially for hydrogenation reaction. Thus, it is very interesting to investigate the different parameter for the formation of nickel phyllosilicate for both gas phase and liquid phase reaction: hydrogenation of carbon dioxide as reaction model for gas phase, selective hydrogenation of furfural to furfuryl alcohol as reaction model for liquid phase.

At present, limitation of fossil fuel resource and global warming are important problems so that many researches have focused on sustainable production of chemicals and fuels from renewable biomass. There is also a growing interest in reducing carbon dioxide levels in the atmosphere because it is well known that carbon dioxide is the main greenhouse gas and increase of its concentration in the air causes global warming which are highly serious problem [31]. There are many routes to reduce CO₂ emission including reduction of the consumption of fossil fuels, carbon capture, separation and storage, and transformation of CO₂ to value added chemical or fuel synthesis [32, 33]. CO₂ methanation is a simple reaction widely used to produce the substitute natural gas. Production of biomethane from carbon dioxide is considered as significant process to increase the value of natural gas (natural gas upgrade) and biogas derived from the fermentation of biomass. This is not only utilize CO₂, but also reduce CO₂ emission. The CO₂ methanation is highly exothermic reaction and there are kinetic limitations [32, 34]. Therefore, the development of catalysts for this reaction is an important factor. Many researches studied the improvement of catalytic performance in this reaction by using various catalysts. CO₂ methanation has been studied using several metal catalysts like Ru, Rh, Pd, Ni, Co, Cu and Fe [31, 33, 35, 36] supported on

various oxide supports such as TiO_2 , Al_2O_3 , SiO_2 , CeO_2 and ZrO_2 [31, 33-35, 37, 38]. Although, noble metal exhibited higher activity for CO_2 methanation, high stability and good resistant to sintering and coke deposition but its high cost and limited availability makes it less attractive as industrial catalysts. Therefore, non-noble metal is interested due to relatively low cost [37]. Ni-based catalyst is one of the non-noble metal based catalysts which favors this reaction and is widely used as the active metal in large scale but it is usually suffered from deactivation due to sintering of nickel particles and carbon deposition in high reaction temperature [39]. To suppress the carbon formation, the high metal dispersion and strong metal-support interaction were reported. Therefore, many attempts have been conducted to improve catalytic performance of Ni-based catalyst, in order to possess both high activity and resistance to coke deposition.

Lignocellulosic biomass is an economical and abundant renewable resource available from agricultural residues. Production of various platform chemicals such as sugar alcohols, organic acids, furfural, and 5-HMF from lignocellulosic biomass via biorefining technologies has been industrially developed [40, 41]. Furfural, synthesized via catalytic dehydration of xylose in hemicellulose, is a versatile platform molecule that can be further converted into many high value derivatives and downstream fine chemicals and biofuels. Around 65% of furfural produced in the world is converted into furfuryl alcohol (FA), which is widely utilized in the manufacturing of fibers, adhesives, resins, fuel additives and can also be employed as an intermediate for the production of plasticizers, vitamin C, farm chemicals and dispersing agents [42, 43]. Due to the presence of both $\text{C}=\text{O}$ and $\text{C}=\text{C}$ bonds in the furfural structure, catalytic hydrogenation of furfural is a relatively complex reaction and undesired products can occur with the use of unsuitable catalysts, resulting in low selectivity to the target products. In recent years, significant progress has been made in the development of

high-performance catalysts with high activities and selectivities for the selective furfural hydrogenation to FA. Although noble metal catalysts such as Pt and Ru show high activities/selectivities under mild conditions [44, 45], their relatively high cost may limit their use in industrial applications. Among the non-noble metal catalysts, nickel has been demonstrated to be a good furfural hydrogenation catalyst due to its excellent H₂ dissociation and relatively low cost. However, nickel-based catalysts without modification/addition of a promoter typically exhibit low selectivity to FA [46, 47] because furfural adsorbs on nickel through both $\eta^1(\text{O})$ -aldehyde and $\eta^2(\text{C},\text{O})$ -aldehyde modes, and as a consequence, both the C=C bonds on the furan ring and the C=O group in furfural are hydrogenated [48, 49]. In addition, Ni catalysts also suffer from poor metal support interactions that can cause leaching of nickel during liquid phase reaction processes, along with agglomeration of nickel species under high reduction temperatures [30, 50]. Developing stable nickel-based catalysts with higher FA selectivity while maintaining high activity and good recyclability is still challenging.

Therefore, in the present study, spherical silica derived nickel phyllosilicate was successfully prepared via one-step modified spherical silica synthesis with cetyltrimethyl ammonium bromide (CTAB) as the structural-directing agent and tetraethoxysilane (TEOS) as the silica source under room temperature to develop catalysts with improved activity and stability. The effect of different loading sequence of Ni and Si source was investigated to study the morphology and the formation of nickel phyllosilicate in gas phase hydrogenation of carbon dioxide. Consequently, the one step synthesized catalysts with various nickel loadings (2 – 30 wt% Ni) by an alternate addition of the nickel and silica sources during the spherical silica synthesis were evaluated in the liquid phase selective hydrogenation of furfural to FA under mild reaction conditions in order to simultaneously obtain excellent anti-leaching property and improve catalytic activity. To highlight the excellence of nickel

phyllosilicate for this method, nickel was loaded on spherical silica for comparison by two step conventional impregnation. Important reaction parameters including reduction temperature and reaction temperature were investigated, seeking to optimize furfural conversion and FA yield. In addition, the characteristics and catalytic properties of prepared catalysts were investigated by several characterization techniques such as XRD, AAS, CO₂-TPD, N₂ physisorption, CO-chemisorption, H₂ chemisorption, SEM, TGA, H₂-TPR, STEM, EDS, and XPS and correlated with the catalyst performances in both reactions. Finally, the stability and recyclability of nickel phyllosilicate catalysts were studied in both reactions.

1.2 Objective of research

The objectives of this research are

1. To investigate the characteristics of nickel phyllosilicate catalysts compared with nickel oxide prepared by conventional impregnation method.
2. To study the preparation method and to synthesize the nickel phyllosilicate catalysts via one-step modified spherical silica synthesis under mild conditions (room temperature and short time)
3. To study the characteristics and catalytic properties of nickel phyllosilicate doped spherical silica with different loading sequences of Ni and Si sources via one-step modified spherical silica synthesis and compared with spherical silica supported NiO via impregnation method in the hydrogenation of carbon dioxide.
4. To study the effect of nickel loading over nickel phyllosilicate containing spherical silica catalysts prepared by one-step modified spherical silica synthesis and

compared with spherical silica supported NiO via impregnation method on the catalytic performance for the liquid phase selective hydrogenation of furfural to furfuryl alcohol.

5. To study the effect of reduction temperature (400-700 °C) and reaction temperature (50-100 °C) on the catalytic properties of spherical silica derived nickel phyllosilicate (Ni_PS) prepared by one-step modified spherical silica synthesis in the liquid phase selective hydrogenation of furfural to furfuryl alcohol.

1.3 Scope of study

Paper I

1. Preparation of spherical silica particles (SSP) under room temperature.
2. Incorporation of 10wt% Ni in SSP by a one-step modified spherical silica synthesis with three different loading sequences: before/alternately/after Si addition during SSP synthesis and calcination in air at 550 °C for 6 h with heating rate of 2 °C/min.
3. Preparation of 10wt% Ni/SiO₂ catalysts by incipient wetness impregnation method for comparison and calcination in air at 550 °C for 6 h with heating rate of 2 °C/min.
4. Pretreatment of the catalysts by reduction with H₂ flow at 500 °C for 3 h.
5. Reaction study of the catalysts in gas phase hydrogenation of carbon dioxide using a fixed-bed quartz reactor under atmospheric pressure at 350-500 °C in steps of 50 °C and kept constant for 1 h at each temperature using WHSV = 36,000 cm³/g_{cat}h and H₂:CO₂ = 10:1.

6. Stability and recyclability of the alternate loading between Ni and Si (Ni_Alt_Si) prepared by a one-step modified spherical silica synthesis under reaction temperature 300 and 450 °C using WHSV = 24,000 cm³/g_{cat}h and H₂:CO₂ = 10:1.

7. Characterization of the catalysts using X-ray diffraction (XRD), N₂ physisorption, CO₂-temperature programmed desorption (CO₂ -TPD), H₂-temperature programmed reduction (H₂-TPR), X-ray photoelectron spectroscopy (XPS), atomic absorption spectrophotometer (AAS), scanning electron microscope (SEM), transmission electron microscopy (TEM), hydrogen chemisorption (H₂-chem) and thermal gravimetric analysis (TGA).

Paper II

1. Preparation of spherical silica particles (SSP) under room temperature.

2. Preparation of spherical silica derived nickel phyllosilicate with nickel loading of 2-30wt% via a one-step modified spherical silica synthesis by an alternate addition of the nickel and silica sources during the spherical silica synthesis and calcination in air at 550 °C for 6 h with heating rate of 2 °C/min.

3. Preparation of 20wt% Ni/SiO₂ catalysts by incipient wetness impregnation method for comparison and calcination in air at 550 °C for 6 h with heating rate of 2 °C/min.

4. Pretreatment of the catalysts by reduction with H₂ flow at 500 °C for 3 h.

5. The effect of reduction temperature in the range of 400-700 °C were studied over 30wt% Ni prepared by a one-step modified spherical silica synthesis.

6. The effect of reaction temperature in the range of 50-100 °C were studied over 30wt% Ni prepared by a one-step modified spherical silica synthesis.

7. Reaction study of the catalysts in liquid phase selective hydrogenation of furfural at 50 °C, 2 MPa and reaction time of 60-300 min using a 160 mL stainless steel Parr autoclave reactor with a Teflon liner.

8. Recyclability study of the 30wt% Ni prepared by a one-step modified spherical silica synthesis (30Ni_PS) and 20wt% Ni prepared by impregnation method (20Ni_Imp) for three cycles run under identical condition at 50 °C, 2 MPa hydrogen pressure for 300 min.

9. Characterization of the calcined, reduced and spent catalysts using X-ray diffraction (XRD), N₂ physisorption, H₂-temperature programmed reduction (H₂-TPR), X-ray photoelectron spectroscopy (XPS), transmission electron microscopy (TEM), and Carbon monoxide chemisorption (CO-Chem).

1.4 Research methodology

1.5 Expected outcome

1. To obtain suitable method for preparation of nickel phyllosilicate with unique structure under mild condition.
2. To understand the characteristic and role of nickel phyllosilicate on the catalytic performance of both liquid phase and gas phase reaction.
3. To obtain suitable nickel phyllosilicate catalysts for liquid phase selective hydrogenation of furfural to furfuryl alcohol and gas phase hydrogenation of carbon dioxide.
4. The results of this research can be the formation and reaction model in gas phase and liquid phase reaction for the future study.

3.1 Abstract

Nickel-doped spherical silica (SSP) catalysts with ca. 10 wt% Ni were prepared via a sol-gel method using cetyltrimethyl ammonium bromide as the structure directing agent with different loading sequences of Ni and Si sources (Si1_Ni2, Ni1_Si2, and Ni_Alt_Si). For comparison purposes, the SSP supported Ni catalysts were also prepared by impregnation method (Ni/SSP (Imp)). All the prepared catalysts showed spherical shape with high specific surface area (357-868 m²/g). The X-ray diffraction and H₂-temperature programmed reduction results revealed the stronger interaction between Ni and SiO₂ in the form of nickel silicate for all the Ni-doped SSP catalysts except Ni/SSP (imp), in which only NiO species were detected. For the reaction temperature 350 °C, the CO₂ conversion was in the order: Ni_Alt_Si (51%) > Ni1_Si2 (49%) > Si1_Ni2 (28%) > Ni/SSP (Imp) (10%) with methane selectivity 80-95%. The superior performances of the Ni_Alt_Si catalyst were correlated well to the higher electron density of Ni on the surface and higher CO₂ adsorption ability as revealed by the X-ray photoelectron spectroscopy and CO₂-temperature program desorption results.

Keywords: CO₂ methanation; Ni/SiO₂ catalysts; Spherical silica; Nickel silicate.

3.2 Introduction

Reduction of carbon dioxide (CO₂) emission, one of the main greenhouse gases to global warming, is the globally concerned topic [31]. This has been done by many routes including reduction of the consumption of fossil fuels, carbon capture, separation and storage, and transformation of CO₂ to value added chemicals or fuel [32, 33]. CO₂ methanation is a simple reaction widely used to produce the substitute natural gas. Production of biomethane from carbon dioxide is considered a significant process to increase the value of natural gas (natural gas upgrade) and biogas derived from biomass fermentation. The CO₂ methanation is highly exothermic reaction and there are kinetic limitations [32, 34]. Therefore, the development of catalysts for this reaction is important and the performances of different metals such as Ru [31], Rh [102], Pd [103], Ni [31, 36], Co [92], and Fe [36] supported on various oxide supports including TiO₂ [38], Al₂O₃ [31, 36], SiO₂ [34, 36], CeO₂ [37, 38, 92], and ZrO₂ [37, 92] have been studied. Nickel-based catalysts are the most widely studied because of their high catalytic activity and relatively low price but they usually suffered from deactivation because of the sintering of nickel particles and carbon deposition [32]. Many attempts have been conducted to improve the catalytic performances of Ni-based catalysts, in order to possess both high activity and resistance to coke deposition.

In a number of studies, formation of nickel silicate species have shown an advantage synergistic effect of both metal and support [104] high dispersion of nickel metal after reduction, high surface area of catalyst, excellent reactivity and stability for hydrogenation reaction. The stronger metal support interaction compared to NiO can also prevent particle agglomeration, [105], which are key parameters for high CO₂ methanation activity. Nickel silicate has been used as catalysts in various reactions such as deoxygenation of methyl palmitate to alkanes [106], carbon dioxide reforming of methane [107], partial oxidation of methane to syngas [105], hydrogenolysis of 5-

hydroxymethyl-2-furraldehyde to yield furanic fuels [108], and waste plastics-derived syngas catalytic reaction [109]. Moreover, Le et al. [34] prepared Ni/SiO₂ catalysts by deposition-precipitation methods and studied in CO and CO₂ methanation. The catalyst exhibited stronger interaction between the nickel species and support than those prepared by a wet impregnation and showed high Ni dispersion due to the availability of nickel silicate species, which resulted in high catalytic activity for both reactions. Lu et al. [110] synthesized a Ni-grafted SBA-15 catalyst with Ni phyllosilicate existing on the SBA-15 surface. The catalysts exhibited higher CO₂ conversion and CH₄ selectivity than the ones containing only NiO species and had high thermal stability for CO₂ methanation.

In the present work, nickel-doped spherical silica (SSP) catalysts were synthesized by modified-sol gel method with cetyltrimethyl ammonium bromide (CTAB) as the structural-directing agent and different loading sequences of Ni and Si source. The sol-gel-derived SSP usually has high surface area with tunable pore size and a narrow pore size distribution [111, 112]. The properties of Ni/SiO₂ catalysts were investigated by X-ray diffraction (XRD), N₂ physisorption, atomic absorption spectrophotometer (AAS), H₂-temperature-programed reduction (H₂-TPR), X-ray photoelectron spectroscopy (XPS), temperature-programmed desorption of CO₂ (CO₂-TPD), transmission electron microscopy (TEM), and their catalytic activities were evaluated in CO₂ methanation.

3.3 Materials and Methods

3.3.1 Preparation of SiO₂ support

SSP supports were prepared according to the procedure given in Ref. [111]. Tetraethoxysilane (TEOS) was used as silica source and CTAB as the structure-directing agent. The SiO₂ support was prepared by gel synthesis with the following molar ratio:

1TEOS: 0.3CTAB: 11NH₃: 58ethanol: 114H₂O. At first, ethanol and aqueous ammonia were added to distilled water (DI) with continuous stirring at room temperature and CTAB was dissolved in this solution. A mixture solution was then stirred for 15 min followed by slow addition of TEOS and the solution was further stirred for 2 h. After that, the white precipitate was separated by filtration, washed with distilled water, dried at 110°C overnight and calcined in air at 550°C for 6 h with a heating rate of 2°C/min.

3.3.2 Preparation of Ni/SiO₂ catalysts by modified sol gel and impregnation method.

Incorporation of 10wt% Ni in SSP were prepared using the modified sol gel method with three different loading sequences during the SSP synthesis. The Ni-doped spherical silica were synthesized using the previous procedure except that nickel nitrate hexahydrate as Ni precursor was added into the solution with sequences as following: adding Ni previous to TEOS, adding Ni and TEOS altogether, and adding TEOS previous to Ni. The obtained catalysts are referred to Ni₁_Si₂, Ni_Alt_Si and Si₁_Ni₂, respectively. Ni/SSP (Imp) was also prepared by a incipient wetness impregnation for comparison as follows, the SSP support was impregnated with an aqueous solution of nickel nitrate, following to drying at 110°C overnight and calcination at 550 °C for 6 h in air.

3.3.4 Catalysts characterization

The X-ray diffraction (XRD) was tested by using a Bruker D8 advance with CuK α Radiation in the 2θ scanning range of 10-90°. Ni loading was determined by atomic absorption spectrophotometer (AAS). The specific surface area, pore volume and pore diameter were determined by N₂ adsorption-desorption measurements with a

Micrometrics ASAP 2020 instrument. H₂-temperature program reduction (H₂-TPR) was used to measure the reduction temperature and reducibility of prepared catalysts. The catalyst samples (0.1g) were pretreated with 30 cm³/min of N₂ flow at 300°C for 1.5 h and then cooled to room temperature. Subsequently, gas mixture of 10%H₂/Ar (30 cm³/min) was introduced to the catalyst while the sample was heated from 30°C to 800°C. After that, TPR profiles were recorded as a function of temperatures. Transmission electron microscopy (TEM) images were obtained with JEOL (JEM-2010) at 200 kV to observe the morphology of the catalysts. X-ray photoelectron spectroscopy (XPS) analysis was employed to investigate the binding energy and surface properties of catalysts with using an AMICUS photoelectron spectrum spectrometer equipped with an MgK_α X-ray as primary excitation and KRATOS VISION2 software. Temperature-programmed desorption of CO₂ (CO₂-TPD) was carried out in a quartz u-tube. 50 mg of the catalysts were reduced at 500°C under H₂ flow for 3 h and then purged with He for 10 min. After that, the catalysts were cooled down to 40 °C with He flow. The CO₂ was introduced to the catalyst samples for 1 h at 40°C to achieve saturation. The samples was then heated from 40°C to 800°C at heating rate of 10°C/min with He flow. Finally, the CO₂-TPD profiles were recorded during increase of temperature. The morphological properties of the support and the prepared catalysts were observed using *scanning electron microscope (SEM)*.

3.3.5 Catalytic activity

The CO₂ methanation reaction was carried out in a fixed-bed quartz reactor under atmospheric pressure. Prior to the reaction test, the catalysts were reduced under H₂ flow with flow rate 30 cm³/min at 500°C for 3 h. The reactant feed were introduced into reactor at H₂/CO₂ ratio of 10/1 with weight hourly space velocity (WHSV) of 36000 cm³/(g_{cat}h) and N₂ was added as an internal standard. The reaction

was performed at the temperature range of 350-500°C in steps of 50°C and then kept constant for 1 h at each temperature. The effluent gases were analyzed by a gas chromatograph with a thermal conductivity detector to separate CO₂, CH₄ and CO.

The catalytic performance was presented as CO₂ conversion and CH₄ selectivity, which were defined as following:

$$X_{CO_2}(\%) = \frac{CO_{2,in} - CO_{2,out}}{CO_{2,in}} \times 100,$$

$$S_{CH_4}(\%) = \frac{CH_4}{CH_4 + CO} \times 100,$$

where X_{CO_2} and S_{CH_4} were CO₂ conversion and CH₄ selectivity, respectively.

3.4 Results and Discussion

3.4.1 Characteristics of the Ni/SiO₂ catalysts

The XRD patterns of Ni/SiO₂ catalysts prepared by the modified sol-gel and impregnation methods are shown in **Fig. 3.1**. The SSP support exhibited only a broad peak, corresponding to amorphous silica. The diffraction peaks at $2\theta = 33.8-36.1^\circ$, 60.8° , which were assigned to nickel phyllosilicate [106], are shown in all the XRD patterns for all the Ni incorporated SSP catalysts. On the other hand, the sharp peaks at $2\theta = 37.2^\circ$, 43.3° , 62.9° , 75.4° and 79.4° , which indicated the characteristic peaks of nickel oxides [32], were found for the Ni/SSP (Imp) catalyst. The formation of the nickel phyllosilicate with low crystallinity were observed on Ni1_Si2, Ni_Alt_Si and Si1_Ni2 catalysts, suggesting that nickel particles were directly incorporated in the SSP during the synthesis to form nickel phyllosilicate. However, the nickel phyllosilicate phases were not detected in the Ni/SSP (imp) due possibly to the higher intensities of the nickel oxide species as compared to nickel phyllosilicate, thus the diffraction peaks of nickel oxide was keen.

Figure 3. 1 XRD patterns of Ni/SiO₂ catalysts after calcined at 550 °C for 6 h.

The N_2 adsorption-desorption isotherms of all the catalysts are shown in **Fig. 3.2**. All the samples exhibited the characteristic type IV isotherms in the IUPAC classification with H1 and H4 type hysteresis loop. The H1 type hysteresis loop describes a cylindrical-shape pore structure [113-115], indicating that the agglomerates or spherical particles arranged in a fairly uniform way. The H4 type loops shows the existence of slit-like pores, indicating that hollow spheres with walls composed of ordered mesoporous silica [114, 115]. The BET surface area, pore diameter, and pore volume of the bare SSP support and the Ni/SiO₂ catalysts are presented in **Table 2.1**. The specific surface area of the catalysts was ranging in the order: SSP (1214 m²/g) > Si1_Ni2 (868 m²/g) > Ni/SSP (Imp) (801 m²/g) > Ni1_Si2 (417 m²/g) > Ni_Alt_Si (357 m²/g). It can be noted that deposition of Ni metal on the SSP support caused a decrease in the surface area and pore volume of the catalysts while pore diameter was not obviously changed. In addition, Si1_Ni2 and Ni/SSP (Imp) showed larger surface area than Ni1_Si2 and Ni_Alt_Si. It is suggested that most of the Ni particles were formed inside the pores of Ni1_Si2 and Ni_Alt_Si samples, resulting in pore blockage and lower pore volume and surface area.

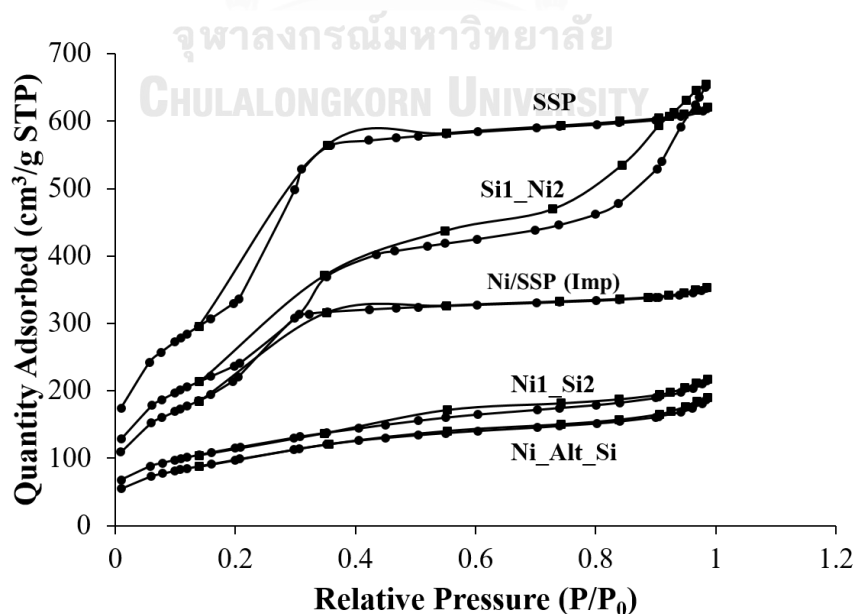

Figure 3. 2 N_2 adsorption isotherms of Ni/SiO₂ catalysts.

Table 3. 1 Physical properties of the Ni/SiO₂ catalysts

| catalysts | BET surface area (m ² /g) | Pore volume (cm ³ /g) | Pore diameter (nm) |
|--------------|---|-------------------------------------|-----------------------|
| SSP | 1214 | 1.08 | 2.01 |
| Ni1_Si2 | 417 | 0.33 | 3.38 |
| Si1_Ni2 | 868 | 1.08 | 3.02 |
| Ni_Alt_Si | 357 | 0.35 | 3.55 |
| Ni/SSP (Imp) | 802 | 0.64 | 2.23 |

*Pore volume and pore diameter determined from the Barret-Joyner-Halenda (BJH) desorption method.

The H₂-TPR was carried out to investigate the reducibility of the catalysts and the interaction between metal and the support. **Fig. 3.3** shows the TPR profiles of the nickel-doped spherical silica catalysts prepared by different loading sequences of Ni and impregnation methods. The peak below 500°C was assigned to the reduction of NiO on a silica support [105], while the high temperature peak (500-800°C) was due to the reduction of Ni²⁺ located in nickel phyllosilicates [17, 105, 108, 116]. For the Ni/SSP (Imp) catalyst, two reduction peaks were observed in the TPR profile. The first peak appears at low temperature (380°C), which can be attributed to the reduction of nickel oxide and a small reduction peak appeared at higher temperature around 580°C. On the other hand, the modified sol gel catalysts showed a board reduction peak in a range of 350-800°C, corresponding to the reduction of nickel phyllosilicates. It can be observed that most of the nickel species on Ni1_Si2, Si1_Ni2 and Ni_Alt_Si were in the form of nickel phyllosilicates, which are in good agreement with the XRD results of the calcined catalysts. In addition, the reduction peak of the modified sol-gel catalysts

were shifted to higher temperatures compared to the impregnation catalyst. Such results indicated that the interaction between the Ni particles and the SiO₂ support were stronger than that of the impregnation catalyst.

Figure 3. 3 H₂-TPR profiles of the Ni/SiO₂ catalysts.

The actual amount of nickel content on the prepared catalysts were determined by using AAS technique to be ca. 10.5-13.9 wt. %. The Ni contents from AAS were close to the amounts of nickel determined by the TEM-EDX. The percentages of metal dispersion as obtained from the hydrogen chemisorption experiments of the Ni-containing spherical silica catalysts are shown in **Table 3.2**. It was found that all the Ni loading by the modified sol gel method led to higher metal dispersion than the Ni/SiO₂ catalyst prepared by the conventional impregnation method.

Table 3. 2 Nickel loading and chemisorption results of the prepared catalysts.

| Catalysts | AAS (Ni, wt. %) | TEM (Ni, wt. %) | Ni dispersion (%) ^a |
|--------------|-----------------|-----------------|--------------------------------|
| Ni1_Si2 | 12.1 | 12.40 | 8.30 |
| Si1_Ni2 | 10.5 | 13.55 | 7.03 |
| Ni_Alt_Si | 11.2 | 10.59 | 9.76 |
| Ni/SSP (Imp) | 13.9 | 14.91 | 5.10 |

^a Determined by hydrogen chemisorption.

**Figure 3. 4** SEM images of Ni/SiO₂ catalysts after calcination.

Figure 3. 5 TEM images of Ni/SiO₂ catalysts after calcination.

The SEM and TEM analysis of the Ni-doped SSP catalysts are shown in **Fig. 3.4** and **3.5**, respectively. The SEM images show that the SSP support and the Ni-doped SSP catalysts exhibited spherical shape with 350-600 nm. The surface of the spherical silica particles was relatively smooth and became roughly spherical after nickel loading. The TEM analysis confirmed the results obtained by SEM analysis that the SSP particles had a spherical shape. After Ni loading, the TEM micrographs showed that the SSP supports were covered by nickel phyllosilicate layer, as shown by fibrous morphology [108], which are in good agreement with the XRD results for all Ni catalysts prepared by the modified sol gel method. According to the BET results, most of Ni species were formed on the surface of Si1_Ni2 thus the layer of nickel silicate was more apparent, compared to the Ni1_Si2 and Ni_Alt_Si catalysts. In the case of the impregnation catalyst, larger nickel particles agglomerated on outer surface of SiO₂ was presented with lower pore volume compared to the bare SSP. In addition, Si1_Ni2 exhibited higher surface area and pore volume than the impregnation catalysts because of the presence of the layered structure of nickel phyllosilicate [17, 108].

XPS analysis was conducted to investigate the chemical state and surface composition on the catalysts. **Fig. 3.6** shows the XPS spectra for Ni-doped spherical silica catalysts after calcination. For the XPS spectra of the Ni/SSP (Imp) catalyst, the binding energy of Ni $2p_{3/2}$ was centered at about 857 eV, which can be attributed to nickel oxide [105, 117]. For Ni $_1$ _Si $_2$, Ni_Alt_Si, and Si $_1$ _Ni $_2$ catalysts, the Ni $2p_{3/2}$ peak was shown at 858.7 eV, which was assigned to Ni $^{2+}$ species in nickel phyllosilicate [106, 118]. In addition, XPS analysis of the Ni/SiO $_2$ catalysts, which were reduced using H $_2$ at 500°C was also carried out. For all the modified sol-gel catalysts, a broad main peak of the Ni $2p_{3/2}$ at around 852-859 eV assigned to nickel metal was observed along with nickel phyllosilicate. According to the TPR results, strong interaction between Ni and SSP in the form of nickel silicate resulted in partial reduction of nickel phyllosilicate to nickel metal at the reduction temperature of 500°C. However, the XPS results showed that the peak corresponding to the binding energy of Ni 2p for Ni $_1$ _Si $_2$ and Ni_Alt_Si shifted to lower binding energy than Si $_1$ _Ni $_2$ catalysts, indicating the electron density of nickel species in Ni $_1$ _Si $_2$ and Ni_Alt_Si were higher than Si $_1$ _Ni $_2$ catalysts. It is noted that higher values of binding energy of the Ni species in this work as compared to the literature may be due to a bias in the calibration using C 1s peak position of the adventitious carbon[119].

Figure 3. 6 XPS spectra of Ni/SiO₂ catalysts after calcination.

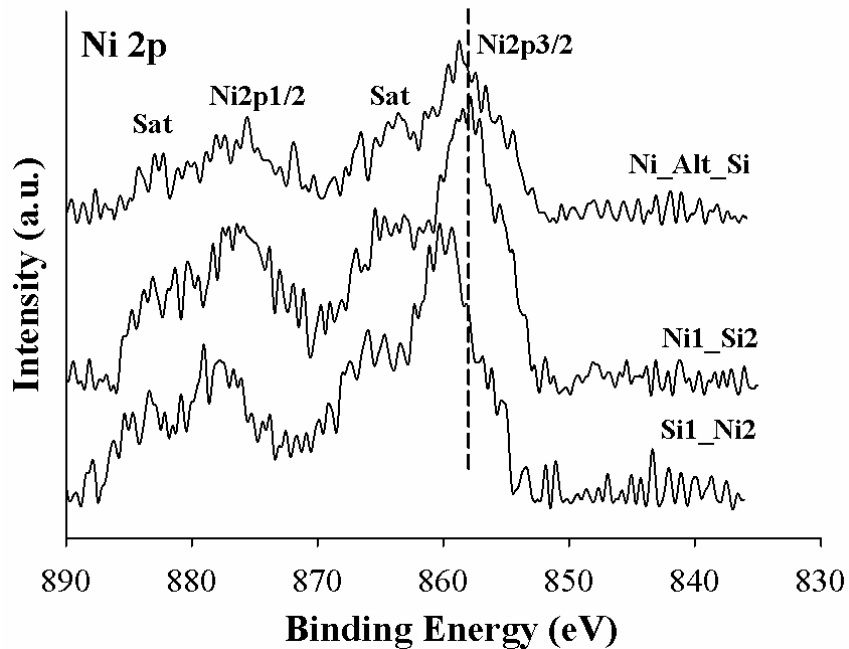

Figure 3. 7 XPS spectra of Ni/SiO₂ catalysts after reduction.

Temperature-programmed desorption of CO₂ was carried out to obtain the CO₂ adsorption ability over the catalysts. The CO₂ TPD results are shown in **Fig. 3.8**. All the prepared catalysts showed only a desorption peak at low temperature in the range of 90 to 200°C. The amount of CO₂ adsorbed on the modified sol gel catalysts was larger than on the impregnation catalyst. This indicated a larger number of active centers on the surface of modified sol gel catalysts, which facilitated the CO₂ dissociation, and as a consequence improved the CO₂ conversion. In addition, oxygenated species may be created by the dissociation of CO₂, which resulted in the elimination of coke deposited and improved stability of the catalysts [34, 120].

Figure 3. 8 CO₂-TPD of Ni/SiO₂ catalysts.

3.4.2 Reaction results

The catalytic performances of the prepared catalysts were tested in the CO₂ methanation. **Fig. 3.9** presents the CO₂ conversion and CH₄ selectivity over the Ni-doped spherical silica catalysts at a WHSV of 36000 cm³/(g_{cat}.h) at the temperature range of 350-500°C as a function of reaction temperature. The catalysts were reduced in the H₂ flowing at 500°C for 3 h prior to the reaction. The CO₂ conversion over all the catalysts increased with increasing reaction temperature and reached a plateau at the reaction temperature at around 500°C. At 350°C, the CO₂ conversion increased in the order: Ni_Alt_Si (~51 %) > Ni1_Si2 (~49%) > Si1_Ni2 (~30 %) > Ni/SSP (Imp) (~10%) with methane selectivity of 80-95%. Despite their lower surface area than the impregnation-catalysts, all the nickel silicate catalysts exhibited superior performances in CO₂ methanation. Prior to the reaction, the catalysts were reduced at 500°C with H₂ flow, which led to partly reduction of nickel phyllosilicate to nickel metal as confirmed by the TPR and XPS results. The existence of both nickel metal and nickel silicate on the catalyst surface appeared to be responsible for the high catalytic performance. Meanwhile, the nickel silicate catalysts may produce metallic nickel with high dispersion after reduction and improved the catalyst stability [17, 105]. Among the silicate catalysts, Ni1_Si2 and Ni_Alt_Si showed high CO₂ conversion at all reaction temperatures with high methane selectivity (90-95%) and the best CO₂ methanation performance was obtained on the Ni_Alt_Si catalyst. It is suggested that the higher electron density of Ni on the surface and the high metal dispersion as well as higher CO₂ adsorption ability over Ni1_Si2 and Ni_Alt_Si catalysts were essential for catalytic activity in CO₂ methanation. In addition, energy of CO₂ desorption from differential scanning calorimetry (DSC) on Ni/SSP (Imp) (1.229 J/g_{cat}) was larger than both of Si1_Ni2 (0.586 J/g_{cat}) and Ni_Alt_Si (0.983 J/g_{cat}), suggesting that too strong interactions between the CO₂ and the catalysts surface resulted to low CH₄ production. Consequently, it can be concluded that the modified sol gel method by Ni and Si source added

alternately during SSP synthesis is a useful method for preparing a highly active and stable Ni-incorporated SSP catalysts for CO₂ methanation.

Figure 3. 9 CO₂ conversion and CH₄ selectivity of Ni/SiO₂ catalysts: Reduced under H₂ at 500°C 3 h, Catalyst = 0.05 g, WHSV = 36000 cm³/g_{cat}h, H₂:CO₂ = 10:1

Figure 3. 10 Catalytic stability and recyclability of the Ni_Alt_Si catalyst. Reaction temperature (a) 300 °C (b) 450 °C. Reduced under H₂ at 500°C 3 h. Reaction condition: Catalyst = 0.1 g, WHSV = 24000 cm³/g_{cat}h, H₂:CO₂ = 10:1. Cycle I: ● CO₂ conversion, ■ CH₄ selectivity Cycle II: ○ CO₂ conversion, □ CH₄ selectivity.

The catalyst stability test was carried out for the Ni_Alt_Si catalyst for 5 h time on stream at 300 °C and 450 °C, WHSV = 24000 cm³/(g_{cat}.h) and the results are shown in **Fig 3.10**. CO was not produced at these temperatures and CO₂ conversion experienced a stable trend with 100% selectivity to CH₄. Comparison of the performances of the Ni-containing spherical silica in this study and the other reported Ni-based catalysts in the CO₂ methanation is shown in **Table 3.3**. Under similar reaction temperature, the performances of catalysts prepared in this study in the form of nickel silicate were comparable to the other supported Ni/NiO catalysts, however, the other reaction conditions such as space velocity, H₂:CO₂, and catalyst weight were varied among the various studies as indicated in the Table. The recyclability of Ni_Alt_Si catalyst was investigated for two reaction-regeneration cycles at a WHSV of 24000 cm³/(g_{cat}.h) and reaction temperature of 300 °C and 450 °C. At temperature of 300 °C, CO₂ conversion increased slightly from 20% in the first cycle to 30% in the second cycle with 100% selectivity of CH₄. Similarly, there was a slight increase of CO₂ conversion from 94% in the first cycle to 98% in the second cycle at reaction temperature of 450 °C. After the

catalytic test, TGA was conducted to examine the formation of coke after reaction test. Very small amount of coke was detected on these catalysts (< 4%).

Figure 3. 11 TGA result of Ni_Alt_Si catalyst conducted in air-containing atmosphere.

3.5 Conclusions

The hydrogenation of CO₂ was studied over Ni-containing spherical silica catalysts prepared with different Ni loading sequences. The prepared catalysts exhibited outstanding textural properties with spherical shape and high specific surface area. Nickel catalysts prepared by the direct incorporation of Ni during SSP synthesis exhibited a stronger interaction between Ni and SiO₂ in the form of nickel silicate, which led to better performances in CO₂ methanation than the SSP supported NiO prepared by conventional impregnation. Alternate loading between Ni and Si (Ni_Alt_Si) resulted in the highest CO₂ methanation activity and methane selectivity due to high electron density of Ni on the surface, high metal dispersion, and high CO₂ adsorption ability.

4.1 Abstract

Enhancing catalytic performance of non-noble Ni catalysts in the selective hydrogenation of furfural to furfuryl alcohol (FA) in terms of furfural conversion, selectivity, and good recyclability is challenging. Here, spherical nickel phyllosilicate catalysts (Ni_PS) with fibrous-like structures, are prepared via a modified sol-gel method with Ni loadings of 2 – 30 wt%. Upon exposure to air, all the reduced Ni_PS catalysts exhibit more than 80% Ni⁰/Ni_{phyllosilicate} species on the surface, whereas a large portion of Ni oxide species (> 55%) is presented on the impregnated catalyst. The Ni²⁺ species in nickel phyllosilicate catalysts are active and highly stable during reduction, reaction, and regeneration, yielding stable catalytic performance for multiple recycle tests in furfural hydrogenation to FA. Furfural conversion over the Ni_PS catalysts increased monotonically with increasing Ni loading without FA selectivity drop. The presence of both metallic Ni⁰ and Ni_{phyllosilicate} also produces a synergistic promotional effect for FA formation.

4.2 Introduction

Nickel is one of the most frequently used metals in a wide variety of industrial manufacturing. Silica supported nickel catalysts (Ni/SiO_2) are used extensively in catalytic reactions due to their low cost, high specific surface area, easy functionalization, and controllable morphology/adjustable pore structures.[1-3] However, Ni/SiO_2 usually suffers from a weak interaction between nickel species and silica supports, which is a significant drawback that can cause leaching of nickel species during liquid phase reaction, as well as agglomeration and sintering of nickel under high thermal treatment and reaction process leading to low catalytic activity, deactivation of catalyst, and poor stability. Several efficient strategies have been reported to improve nickel dispersion and enhance the metal-support interaction such as the addition of various promoters such as La_2O_3 [7] and V_2O_5 , [6] the formation perovskite and hydrotalcite structures, [11, 12] the modification of the support and develop preparation method to enhance metal-support interaction and inhibit the catalyst agglomeration such as molecular layer deposition (MLD), [10] the construction of nickel-based catalysts with a confinement effect like mesostructured cellular foam (MCF). [11] However, there are still some limitation for these methods such as high cost, complicate procedure, requires multiple steps and unique instruments for preparation.

Metal phyllosilicates have received considerable attention in recent catalysis research because of their unique layered structure that can offer outstanding properties such as strong metal-support interaction, small metal domain size and high dispersion of active metal species, rich porous structures, excellent adsorption properties, high thermal stability, and simple preparation procedures. Ni phyllosilicates typically possess a lamellar structure, consisting of tetrahedral layers of SiO_4 (Si-O-Si) and octahedral layers of Ni (II) (Ni coordinated to oxygen atoms or hydroxyl groups, Si-O-Ni-O(OH)). [121] It has been reported that metallic nickel derived from the reduction

of nickel phyllosilicate can provide nickel particles with fine size at high nickel content and high dispersion. The Ni phyllosilicates show good performances in a number of reactions including CO₂ and CO methanation,[16] hydrogenation of levulinic acid to γ -valerolactone,[28] xylose hydrogenation to xylitol,[24] hydrogenation of maleic anhydride,[15] hydrogenation of polycyclic aromatic hydrocarbons,[29] and carbon dioxide reforming of methane.[30]

Generally, nickel phyllosilicates with different crystal structures can be synthesized via various methods including hydrothermal methods,[1, 5, 14, 19] the ammonia evaporation method,[20-22] deposition-precipitation methods [23, 24] and sol-gel method [25] though the reaction between nickel precursor and silica materials. Among which, the hydrothermal method has been employed for preparation of nickel phyllosilicate catalysts due to high crystallinity, handy experimental operation, environmentally friendly, and uniform dispersed of nickel phyllosilicate. However, conventional hydrothermal reaction is carried out in an autoclave under harsh hydrothermal conditions at high temperature (>180 °C) with long reaction time (> 24 h), resulting in the loss of surface silanol group, limited nickel loading (even though there are excess nickel and silica amount),[7, 19, 26, 27] small amount of nickel phyllosilicate being formed, and large particles at relatively low hydrothermal temperatures (e.g. 120 and 160 °C).[16] Thus, it is a great challenge to improve and synthesize Ni phyllosilicates with high nickel contents under mild conditions and remain the superiority properties of nickel phyllosilicate. Chen et al. [5] synthesized nickel phyllosilicate with high nickel contents (22.4 wt%) using urea-assisted hydrothermal method under mild hydrothermal temperature and reaction time (180 °C, 24 h). The quick formation of nickel phyllosilicate was obtained because urea facilitate the formation of Ni(OH)₂ and leaching of SiO₂. Then, they [4] synthesized nickel phyllosilicate via the hydrothermal method assisted by NH₄F and urea, which optimal

nickel phyllosilicate (N/D-120-12) exhibited high catalytic performance for CO₂ methanation and excellent anti-sintering property. They reported that ammonium fluoride and urea can be efficient accelerators of the formation of H₄SiO₄ and Ni(OH)₂, respectively which are essential intermediates for the formation of nickel phyllosilicate. Nickel phyllosilicate could be formed under mild hydrothermal conditions at 100 °C for 12 h by double accelerators of ammonium fluoride and urea [1] which has similar morphology and nickel content with conventional hydrothermal method at 220 °C for 48 h. Although, these modified hydrothermal methods can improve hydrothermal conditions, there are still some limitations of complicated operation procedures and too low hydrothermal conditions provide low nickel content and small amounts of nickel phyllosilicate formation.[4]

Moreover, the preparation of nickel phyllosilicate usually consists of two major steps: step (1) silica material synthesis and step (2) nickel phyllosilicate formation via the reaction of silica material and nickel precursor. It consumes large amounts of reagent and energy and requires long operation time. One-pot synthesis of Ni phyllosilicates has recently been reported, for example, Chen et al. [26] prepared 3D-SBA-15 derived Ni phyllosilicate via one-pot and two-pot hydrothermal methods at 180 °C. One-pot synthesis exhibited small size nickel particles and showed high anti-sintering due to strong metal-support interaction derived from nickel phyllosilicate. Many advantages of one-pot synthesized nickel phyllosilicate catalyst (Ni/S-O) were achieved including low cost, monolithic appearance, fine nickel particle size, high nickel phyllosilicate content, high convenience and elimination of the separation, drying and calcination processes. In addition, it was found that hydrothermal conditions were significant factors for the formation of nickel phyllosilicate via one-pot synthesis, which sectional hydrothermal at 100 °C, 24 h and 180 °C, 24 h affected the formation of nickel phyllosilicate in their work.

In this study, spherical silica derived nickel phyllosilicate (Ni_PS) was successfully prepared via one-step modified spherical silica synthesis with alternate addition of nickel and silica precursor under room temperature. The one step synthesized Ni_PS catalysts with various nickel loadings (2 – 30 wt% Ni) were characterized by H₂-TPR, STEM, EDS, and XPS and their catalytic properties were evaluated in the liquid phase selective hydrogenation of furfural to furfuryl alcohol (FA) under mild reaction conditions in order to simultaneously obtain excellent anti-leaching property and improve catalytic activity. Furfural, synthesized via catalytic dehydration of xylose in hemicellulose, is a versatile platform molecule that can be further converted into many high value derivatives and downstream fine chemicals and biofuels. Among the non-noble metal catalysts for furfural hydrogenation, Ni has been demonstrated to be a good furfural hydrogenation catalyst due to its excellent H₂ dissociation and relatively low cost.

4.3 Results and discussion

4.3.1 Characterization of the calcined catalysts

The presence of nickel phyllosilicate and nickel oxide on the prepared catalysts was probed by XRD and the results are shown in **Figure 4.1**. A broad peak located at $2\theta=23^\circ$, which is a characteristic peak of amorphous oxide, was observed for all the samples. The catalysts prepared by one-step modified spherical silica synthesis display the major diffraction peaks at 2θ degrees = 34.1 and 60.8, which are attributed to the nickel phyllosilicate structure.[30] The intensity of the characteristic diffraction peaks of nickel phyllosilicate increased with increasing nickel loading from 10-30 wt% and was not observed with low nickel loading (2-5wt%) may be due to small amount /low crystallinity of nickel phyllosilicate (**Figure 4.1A**). On the other hand, the sharp diffraction peaks assigned to nickel oxides were clearly evident as expected at $2\theta =$

37.3°, 43.3°, 62.8°, 75.5° and 79.3° [32] in the XRD patterns of the 20Ni_Imp catalyst. The oxidation states of nickel species on the catalyst surface before reduction/passivation were analyzed by XPS and the results are shown in **Figure 4.1**. As shown in **Figure 4.1B**, the Ni 2p_{3/2} peaks of the calcined 20Ni_Imp were deconvoluted into two peaks at the binding energy 854.2 eV and 856.2 eV, which were assigned to aggregated NiO and highly dispersed Ni²⁺, respectively.[22, 122] For all the calcined Ni_PS catalysts, the observed strong peaks at around 857-859 eV were assigned to Ni²⁺ species that strongly interact with silica in the nickel phyllosilicate structure.[30] The XPS peak intensity can be used to indicate the different levels of nickel dispersed on catalyst surface.[105] The results demonstrate that nickel phyllosilicate phase was successfully obtained by one-step modified spherical silica synthesis even for relatively low nickel content (2 wt%) under mild conditions (room temperature and short time).

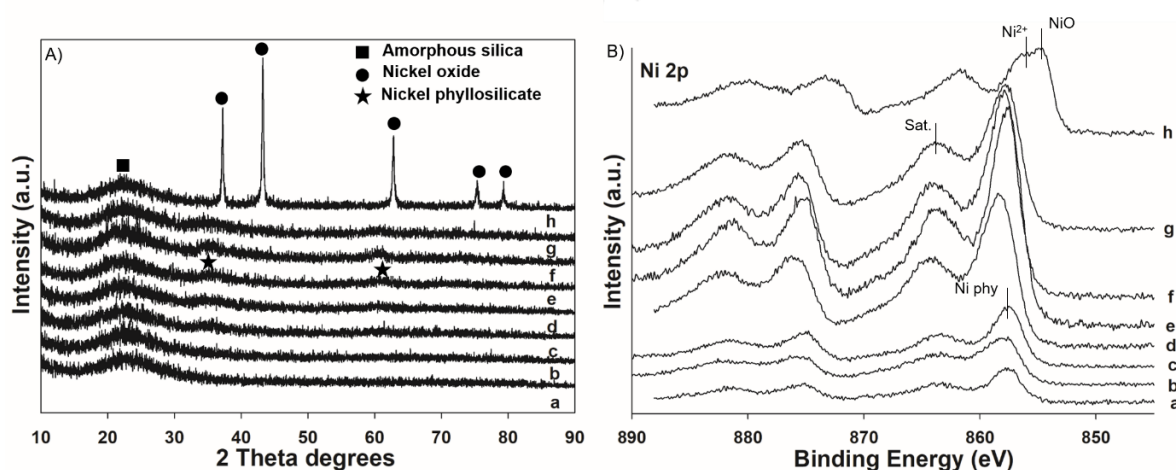

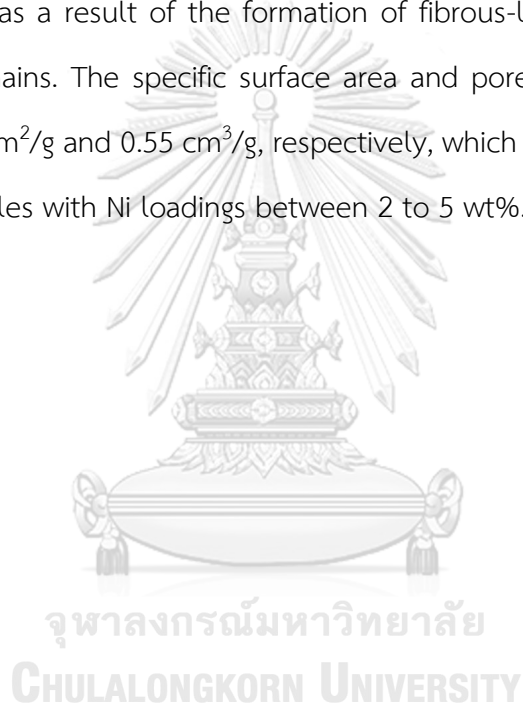

Figure 4. 1 A) XRD patterns and B) Ni 2p XPS spectra of the calcined catalysts (a) 2Ni_PS, (b) 5Ni_PS, (c) 10Ni_PS, (d) 15Ni_PS, (e) 20Ni_PS, (f) 25Ni_PS, (g) 30Ni_PS, (h) 20Ni_Imp

The structures and morphology of the calcined catalysts are shown in the TEM images in **Figure 4.2**. All the prepared catalysts displayed a spherical particle shape, with average size ca. 0.30 μm for the series of Ni_PS. The average particle size was

slightly decreased with increasing nickel loading ($\sim 0.2 \mu\text{m}$ for 30Ni_PS) and was ca. $0.5 \mu\text{m}$ for the 20Ni_Imp catalyst. Owing to simultaneous loading of nickel and silica precursors during one-step modified spherical silica synthesis, nickel can form within the structure and on the surface, and nickel density were increased from the unique structure of nickel phyllosilicate that interfere with each other, resulting in smaller particle size with increasing nickel loading. According to the literature, the decrease of particle size of mesostructured silica nanoparticles (MSN) resulted to the improved formation of nickel phyllosilicate due to the increase of surface silanol group concentration.[123] A fibrous-like structure was observed on the nickel phyllosilicate catalysts, whereas on the impregnated catalysts, large metal oxide particles ($d_p \sim 60 \text{ nm}$) were formed on the spherical silica support. It is confirmed that nickel phyllosilicate was successfully formed under relatively mild conditions. The N_2 physisorption results and the corresponding nitrogen adsorption-desorption isotherms are shown in **Table 4.1** and **Figure S4.1**. The specific surface area, pore volume, and pore size diameter of the bare spherical silica support are $1084 \text{ m}^2/\text{g}$, $0.79 \text{ cm}^3/\text{g}$, and 2.6 nm , respectively. Compared to the bare SiO_2 , all the Ni_PS catalysts with 2 – 30 wt% Ni loading possessed lower BET surface areas and smaller pore volumes with slightly larger average pore diameters. The BET surface area and pore volume decreased from 977 to $168 \text{ m}^2/\text{g}$ and 0.77 to $0.06 \text{ cm}^3/\text{g}$ with increasing Ni loading from 2 wt% to 10 wt% and then were slightly increased to reach $260 \text{ m}^2/\text{g}$ surface area and $0.15 \text{ cm}^3/\text{g}$ pore volume for the 30Ni_PS sample. Typically, the formation of the fibrous-like structure of nickel phyllosilicates can result in an increased specific surface area and pore volume, compared to the silica support and impregnation based catalysts.[15, 108, 121] This correlates with a unique porous structure for the lamellar nickel phyllosilicate. However, a different trend was observed in the present work. Here, nickel phyllosilicate was formed by simultaneous loading of nickel and silica

precursors during the one-step modified spherical silica synthesis with CTAB as the structure directing agent, followed by calcination at 550 °C for 6 h. For Ni loadings \leq 10 wt% on the spherical silica, the higher surface area could be attributed to the mesostructured SiO₂ being formed in addition to the nickel phyllosilicate phase, as confirmed by the presence of mesopores in the adsorption isotherm. Samples with larger nickel loadings lacked mesopores according to the nitrogen physisorption isotherms. Further increases of Ni loading to 15, 20, 25, and 30 wt% led to increasing BET surface area, as a result of the formation of fibrous-like structure of the nickel phyllosilicate domains. The specific surface area and pore volume of the 20Ni_Imp catalyst were 828 m²/g and 0.55 cm³/g, respectively, which were comparable to those of the Ni_PS samples with Ni loadings between 2 to 5 wt%.

CHULALONGKORN UNIVERSITY

The reducibility of both Ni_PS and 20Ni_Imp catalysts was further investigated by H₂-TPR and the results are shown in **Figure 4.3**. The impregnation catalyst exhibited two reduction peaks, a strong reduction peak at 342 °C and a weak shoulder peak at around 489 °C, which are attributed to reduction of the nickel oxide species and the weak interaction between isolated nickel ions (Ni²⁺) and SiO₂, respectively.[22] Interestingly, all the Ni_PS catalysts exhibited only broad reduction peaks in the high temperature ranges from 500 °C to 800 °C, which are assigned to the reduction of Ni²⁺ located in the nickel phyllosilicate with strong interaction between nickel species and

silica.[22] These nickel species existed mostly in the form of strong, chemically bonded Ni-O-Si species in the nickel phyllosilicate structure. Additionally, the reduction peak tended to shift to higher temperature and larger area with increasing nickel loading from 2 to 30 wt% indicating the more nickel phyllosilicate and more difficult to be reduced. The H₂-TPR results suggest the incomplete reduction of nickel species to metallic metal for all catalysts during the reduction process at 500 °C for 3 h prior to the reaction tests.

Figure 4. 3 H₂-TPR profiles of the calcined catalysts (a) 2Ni_PS, (b) 5Ni_PS, (c) 10Ni_PS, (d) 15Ni_PS, (e) 20Ni_PS, (f) 25Ni_PS, (g) 30Ni_PS, (h) 20Ni_Imp

4.3.2 Characterization of the reduced catalysts

After reduction with H₂ at 500 °C for 3 h (**Figure 4.4**), the distinct XRD peaks at $2\theta = 44.6^\circ$, 51.8° and 76.2° observed on the 20Ni_Imp are ascribed to metallic nickel,[50] indicating that the crystalline nickel oxides on the impregnation catalyst were primarily reduced to nickel metal. On the series of reduced/passivated Ni_PS

catalysts, the diffraction peaks of nickel phyllosilicate were moderately weakened and disappeared for the Ni_PS with nickel loadings $\leq 10\text{wt}\%$. Small diffraction peaks corresponding to metallic nickel were additionally detected on the reduced Ni_PS with relatively high Ni loading (e.g., $\geq 15\text{ wt}\%$ Ni). Such results indicate the co-existence of nickel phyllosilicate and nickel metal on the reduced Ni_PS, whereas the crystalline nickel oxide species appeared totally reduced into metallic nickel on the 20Ni_Imp. In addition, the morphology of the reduced/passivated catalysts are shown in the TEM images in **Figure 4.2** along with the elemental mapping of Ni and Si species on the catalysts. Small bright spots representing nickel metal domains were well distributed on both types of reduced samples. As shown in **Figure 4.2f-h**, high dispersion of small nickel particles on the catalyst surface without any large aggregation was observed over 20Ni_PS, in addition to the fibrous-like structure of the nickel phyllosilicate, which remained after reduction. The TEM results are consistent with the XRD and H_2 -TPR results, showing that the nickel phyllosilicate species were not completely reduced under the reduction conditions used in this work. The average diameters of the nickel particles on the reduced catalysts as well as their size distribution histograms are shown in **Figure 4.2i** and **j**. The average nickel particles after reduction at $500\text{ }^\circ\text{C}$ for the reduced 20Ni_PS and 20Ni_Imp are 3 nm and 29 nm, respectively. It can be implied that the remaining of nickel phyllosilicate layer after reduction process act as the support on metallic nickel which resulted in the highly dispersed nickel particles with small size of homogeneous nickel particle at high loading.[108] The nickel phyllosilicate catalyst is highly resistant to sintering and high stability because of the enhanced interaction of Ni and SiO_2 in the nickel phyllosilicate layers, preventing agglomeration under high temperature reduction processes such as the method deployed here.[19, 22, 30]

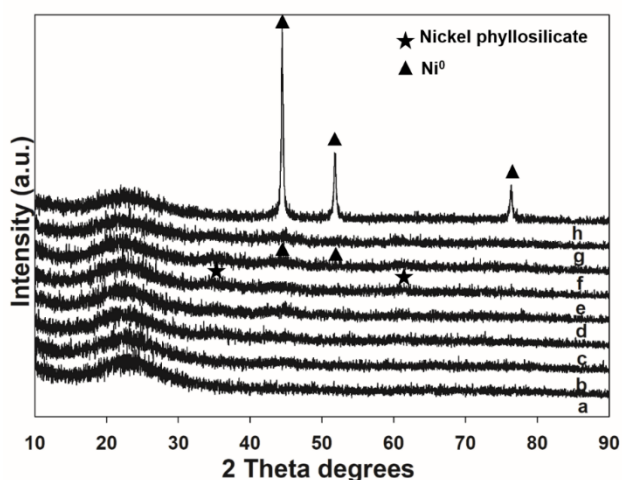

Figure 4. 4 XRD patterns of the reduced catalysts (a) 2Ni_PS, (b) 5Ni_PS, (c) 10Ni_PS, (d) 15Ni_PS, (e) 20Ni_PS, (f) 25Ni_PS, (g) 30Ni_PS, (h) 20Ni_Imp

The Ni 2p XPS spectra of the reduced/passivated catalysts were deconvoluted into five peaks as shown in **Figure 4.5**. The first peak at 853.3 eV is assigned to Ni⁰ species. The binding energy at 855.8 eV belongs to highly dispersed of Ni²⁺ and the strong peak at around 857.6 eV and 859.0 eV were ascribed to Ni²⁺ species with strong interactions with SiO₂ in nickel phyllosilicate structure. The last peak centered at 862 eV is attributed to the Ni 2p satellite peak due to electron shake-up.[15] As also revealed by H₂-TPR results, the nickel phyllosilicate species could not be totally reduced at 500 °C, thus, the XPS peaks corresponding to nickel phyllosilicate domains were still apparent on the catalysts after reduction/passivation. For the reduced/passivated 20Ni_Imp, the Ni 2p_{3/2} peaks were deconvoluted into three typical nickel species at binding energies of 852.8, 854.5, 855.9-856.9 eV, which corresponded to metallic nickel Ni⁰, NiO, and highly dispersed Ni²⁺, respectively.[7, 22] Comparing to the metallic Ni⁰ peaks of the 20Ni_Imp at 852.8 eV, the Ni⁰ peaks of the Ni_PS catalyst were shifted to a higher binding energy at 853.3 eV, indicating a stronger interaction between nickel metal and the silica support of the nickel phyllosilicate catalysts. Such results are in good agreement to the well-established trend in the literature.[124] The

surface atomic ratios of $Ni_{(total)}/Si$, Ni^0/Si , $(NiO+Ni^{2+})/Si$, and $Ni_{Phyllosilicate}/Si$ of the various catalysts are provided in **Table 4.2**. The surface atomic ratios of $Ni_{(total)}/Si$ on the Ni_PS catalysts increased with increasing Ni loading and appeared to reach a threshold limit at around 20-25 wt% Ni. For a similar Ni loading (20 wt% Ni), the surface atomic ratio of Ni^0/Si on the reduced/passivated 20Ni_PS catalysts is lower compared to the reduced/passivated impregnation catalyst (20Ni_Imp), which is consistent with the H₂-TPR results showing that the impregnation catalyst was easier to reduce than the nickel phyllosilicate materials. However, the surface atomic ratios of $Ni_{(total)}/Si$ on 20Ni_PS was twice that of 20Ni_Imp, indicating a large amount of Ni phyllosilicate species on the catalyst surface. Moreover, all the reduced Ni_PS catalysts still exhibit more than 80% $Ni^0+Ni_{Phyllosilicate}/Ni_{total}$ species on the surface, whereas a large portion of Ni oxide species (> 55%) is presented on the impregnated catalyst. CO pulse chemisorption was performed to evaluate the number of potential Ni active sites on the catalysts, assuming that one CO molecule adsorbed on one nickel site, and the results are reported in **Table 4.1**. On the calcined catalysts, the amounts of CO adsorbed on the calcined 20Ni_Imp and 20Ni_PS were 1.8 $\mu\text{mol/g}$ and 37.6 $\mu\text{mol/g}$, respectively. It is suggested that CO cannot adsorb on bulk nickel oxides but can adsorb on nickel phyllosilicate domains. The amounts of CO adsorbed on the reduced catalysts are as follows: 2Ni_PS (10.3 $\mu\text{mol/g}$), 5Ni_PS (10.4 $\mu\text{mol/g}$), 10Ni_PS (9.8 $\mu\text{mol/g}$), 15Ni_PS (10.8 $\mu\text{mol/g}$), 20Ni_PS (35.8 $\mu\text{mol/g}$), 25Ni_PS (26.5 $\mu\text{mol/g}$), 30Ni_PS (19.3 $\mu\text{mol/g}$). The amounts of CO adsorbed on the Ni_PS catalysts with 2-15 wt% Ni were quite similar, being around 10 $\mu\text{mol/g}$. The amount of CO adsorbed was maximized on the 20 wt% nickel loading, 20Ni_PS catalyst, at 35.8 $\mu\text{mol/g}$, which was much higher than the 20Ni_Imp (11.38 $\mu\text{mol/g}$). Further increase of Ni loading to 25 and 30 wt% resulted in a decline of adsorbed CO to around 20 $\mu\text{mol/g}$. Nevertheless, the results suggest that both metallic Ni^0 and Ni^{2+} in the phyllosilicate structure were active for CO

chemisorption and may provide high active sites for furfural hydrogenation reaction. It can be seen that this work provides simple one-step strategy for the synthesis of spherical silica derived nickel phyllosilicate at room temperature, which still exhibited unique property of nickel phyllosilicate.

4.3.3 Catalytic test results

The catalytic performances of the prepared catalysts were evaluated in the selective hydrogenation of furfural to FA at 50 °C under H₂ pressure of 20 bar for 5 h with methanol as the solvent. All the catalysts were reduced at 500 °C under H₂ flow for 3 h and passivated prior to the reactions. Furfural is an interesting biomass platform molecule that contains several functional groups in its structure, which can be hydrogenated to various products. The desired product in this work is FA, while THFA was found as a minor product. The blank test result is shown in **Table S4.1**, 2-furaldehyde dimethyl acetal was the only by-product obtained (~ 6% conversion) which was produced by the solvent reaction via acetalization mechanism.[44, 125] The influence of nickel loadings in the range of 2-30 wt% Ni in the Ni_PS catalysts on furfural conversion, selectivity, and FA yield as a function of reaction time are shown in **Figure 4.6**.

Typically, furfural conversion and FA selectivity over nickel catalysts increase with increasing nickel loading up to an optimum amount (e.g. 4.6%Ni in the Ni-Cu/ZrO₂ catalyst [126] and 10%Ni/CNT),[46] then decrease with further increases of nickel content, which is possibly due to agglomeration of Ni particles at high Ni loadings resulting in low metal dispersion/low activity.[12] Interestingly, furfural conversion of all the Ni_PS catalysts monotonically increased with increasing nickel loading from 2 to 30 wt% Ni. Although the CO chemisorption and XPS results suggest the largest availability of active sites and the highest Ni⁰/Si on the surface at 20 wt% Ni loading, furfural conversion continued to increase on 30Ni_PS comparing to 20Ni_PS and 25Ni_PS. For a similar Ni loading at 20 wt%, 20Ni_Imp exhibited a higher hydrogenation rate than 20Ni_PS. Furfural conversion over 20Ni_Imp and 20Ni_PS after 5 h of reaction time were 58% and 48 %, respectively. However, it can be clearly seen that all the nickel phyllosilicate catalysts exhibited higher FA selectivity (65-75%) than 20Ni_Imp

($\sim 48\%$ FA). The selectivity of THFA on all the Ni_PS catalysts was below 10% (except for 30Ni_PS, where the THFA selectivity was $\sim 13\%$) while that of 20Ni_Imp was $> 15\%$. According to the literature, and as shown in **Figure 4.6**, the selectivity of FA and THFA did not depend on furfural conversion and reaction time and was rather affected by the electronic properties of Ni species and/or Ni-support interaction.[61, 70, 127-129]

Figure 4. 6 Hydrogenation of furfural to FA over nickel phyllosilicate catalysts with varying nickel loading and impregnation catalyst (20Ni_Imp) versus reaction time. Reaction conditions: 250 mg catalyst, 3 mmol furfural, 50 ml methanol solvent, 0.4 mmol dodecane, reaction temperature 50 °C, 20 bar H₂ pressure, reaction time 5 h and catalysts were reduced at 500 °C

A proposed reaction pathway for furfural hydrogenation over Ni-based catalysts is shown in **Figure S4.2**. Hydrogenation of carbonyl group (C=O) in furfural produces the desired product FA and further hydrogenation of FA (C=C) results in THFA. Other by-products such as furan, tetrahydrofuran, methyl furan, etc. are produced in a small amount (total selectivity $\leq 10\%$). The carbon balances (**Table S4.1.**) were calculated above 85 % over all samples for each time point. Typically, supported Ni catalysts without modification/addition of a promoter produce higher selectivity towards THFA than FA (76-91% selectivity of THFA).[46, 47] The use of high surface area spherical silica in this study can enhance FA selectivity of the impregnated Ni/SiO₂ catalysts since significant amounts of highly dispersed Ni²⁺ species were formed on the 20Ni_Imp catalyst, as revealed by the XPS results. Based on the catalyst characterization and reaction results, nickel phyllosilicate species were active for both CO chemisorption and also for furfural hydrogenation under mild reaction condition. Synergistic of highly dispersed nickel particles and Lewis acid sites of the remaining nickel phyllosilicate contributes to the low-temperature hydrogenolysis/hydrogenation in biomass conversion.[108, 121] For the same Ni loading (20 wt% Ni), the amount of CO adsorbed on 20Ni_PS was much higher than 20Ni_Imp, despite its lower hydrogenation activity. The larger amounts of CO chemisorption on the Ni_PS catalysts were correlated to the larger amounts of Ni phyllosilicate being formed, and not the higher hydrogenation activity. In other words, the Ni_PS exhibited higher CO chemisorption ability but the hydrogenation activity of Ni phyllosilicate species was lower than metallic Ni⁰. It is widely accepted that metallic Ni⁰ function as active sites for H₂ dissociation [15, 29, 66] while Ni²⁺ in NiO is inactive. However, Ni²⁺ species that are strongly interacting with SiO₂ can play an important role in binding and activating the C=O group in the furfural structure, as suggested by CO chemisorption results. The electron-deficiency of some Ni²⁺ atoms may allow them to act as Lewis acid sites for the adsorption of the C=O bond through oxygen atoms, which likely enhances the adsorption and conversion of

furfural.[80] The presence of both metallic Ni⁰ and highly dispersed Ni²⁺ that strongly interact with SiO₂ is suggested to be necessary for high furfural conversion and high FA selectivity under mild reaction condition.

Loading of 20 wt% Ni by impregnation on high surface area spherical silica resulted in about 50:50 metallic Ni⁰ species: (NiO/highly dispersed Ni²⁺) as revealed by XPS results. As a result, the 20Ni_Imp catalyst exhibited relatively high conversion of furfural but the selectivity of FA was lowest among the catalysts studied, producing the highest %THFA. The 20Ni_PS (78% Ni phyllosilicate species, 5% Ni⁰) showed lower activity with higher FA selectivity and as a consequence the FA yield was essentially similar to that of 20Ni_Imp. This is because the hydrogenation activity of Ni phyllosilicate is lower than metallic Ni⁰. However, increasing the Ni loading on Ni_PS to 30 wt% can further increase the furfural conversion without any change in FA selectivity, resulting in much higher FA yield on the 30Ni_PS.

4.3.4 Catalyst Recyclability Tests

The recyclability of the catalysts was investigated on the 30Ni_PS and 20Ni_Imp catalysts by conducting three cycles run under identical conditions at 50 °C under 20 bar H₂ pressure for 5 h. After use, the spent catalysts were washed with methanol solvent several times and were subjected to H₂ reduction at 500 °C for 3 h before being reused for furfural hydrogenation. The recyclability results are shown in **Figure 4.7**. It is clear that the 30Ni_PS exhibited excellent recyclability for furfural hydrogenation with enhanced FA selectivity. The conversion decreased slightly (by ~10%) while FA selectivity increased from 64% to 74% in the third cycle. On the other hand, the 20Ni_Imp catalyst showed poor reusability. Furfural conversion drastically declined from 58% for the fresh catalyst to 29% in the third cycle (~ 50% change) with a significantly drop of FA selectivity from 48% to 32% in the third run.

Figure 4. 7 The recycle test for the hydrogenation of furfural to FA over 30Ni_PS and 20Ni_Imp catalysts with three repeated runs. Reaction conditions: 250 mg catalyst, 3 mmol furfural, 50 ml methanol solvent, 0.4 mmol dodecane, reaction temperature 50 °C, 20 bar H₂ pressure, reaction time 5 h and catalysts were reduced at 500 °C.

The spent catalysts after three runs were further characterized by TEM and XPS to examine the changes in the characteristics of the catalysts after reaction and the results are shown in **Figure S4.3**, **Figure S4.4** and **Table S4.2**. TEM images confirm that there were no significant changes in the morphology of the spent 30Ni_PS catalyst, in which spherical particles of 0.19 μm covered by nickel phyllosilicate layers were evidently observed. The average nickel particle size was slightly increased from 2.9 to 3.1 nm after the third cycle of reaction tests. It has been suggested that the fibrous nickel phyllosilicate structure can inhibit the growth of nickel particles and prevent the sintering/leaching of nickel particles during CO₂ methanation [19] and hydrogenation of maleic anhydride.[15] In contrast, the average Ni particle sizes on 20Ni_Imp increased from 29 nm to 35 nm, indicating that agglomeration of Ni particles on the silica support occurred under reaction conditions as a result from weaker interaction between nickel and the silica support, which led to a decline in the catalytic performance for each run. The XPS spectra of the used 30Ni_PS catalyst confirmed the presence of nickel metal and nickel phyllosilicate domains after the third run. There was no obvious

change in the XPS spectra before and after the reaction tests. The high stability of Ni_PS catalysts was ascribed to strong metal-support interaction and unique properties of Ni phyllosilicate that the unreduced Ni²⁺ could serve as a good support for the Ni⁰ species, resulting in the active metallic nickel highly dispersed with small size nickel particle.[108] However, the atomic surface ratio of Ni⁰/Si species increased from 0.36 to 0.57 on the 30Ni_PS whereas that of 20Ni_Imp decreased from 2.1 to 1.4. It is suggested a lower Ni dispersion on the spent 20Ni_Imp. Such results also suggest that nickel phyllosilicate species could be reduced into metallic Ni⁰ during reaction on the 30Ni_PS, which was still beneficial for reaction. The good recyclability of the Ni_PS catalysts was attributed to the strong interaction between nickel and the silica support and the high stability of the nickel phyllosilicate species that can prevent agglomeration of Ni particles during reaction and re-reduction.[7, 15, 24]

4.3.5 Effects of reduction temperature and reaction temperature

The effects of reduction temperature and reaction temperature in the selective hydrogenation of furfural to FA were further investigated on the 30Ni_PS catalyst. Prior to the reactions, the 30Ni_PS catalyst was reduced under H₂ at 400–700 °C. The catalyst reduced at 400 °C yielded low furfural conversion. The highest furfural conversion and FA selectivity were obtained after 5 h of reaction time on the catalysts reduced at temperatures between 500–600 °C. Further increasing the reduction temperature to 700 °C led to a drop of furfural conversion, despite the larger amount of metallic Ni⁰ formed (from TPR and XPS results). Interestingly, the catalysts reduced at relatively high reduction temperatures (500, 600, and 700 °C) maintained their high selectivity to FA, varying from 60-70% during the 5 h reaction time with negligible amounts of THFA and undesired products.

Figure 4. 8 Hydrogenation of furfural to FA at different reduction temperatures over 30Ni_PS catalysts. Reaction conditions: 250 mg catalyst, 3 mmol furfural, 50 ml methanol solvent, 0.4 mmol dodecane, reaction temperature 50 °C, 20 bar H₂ pressure, reaction time 5 h

The reduced catalysts were characterized by TEM, BET, and XPS analyses to correlate their characteristics with the catalytic performances. From the TEM results, the nickel phyllosilicate layers still existed on the surface of the 30Ni_PS catalysts. The average nickel particle sizes were slightly increased from 2.9 nm to 3.2 nm with increasing reduction temperature from 500 °C to 700 °C (**Figure S4.5**), but were still much smaller than the reduced 20Ni_Imp catalyst, as shown in **Figure 4.2**. Such results suggest that the reduction temperature has little effect on the particle size of metallic nickel being formed. The BET surface area, pore volume, and pore diameter of the reduced catalysts are presented in **Table S4.3**. There were no major differences in the structural properties of the reduced catalysts. They had similar average nickel particle sizes of ca. 3 nm with BET surface areas 236-257 m²/g, pore volumes 0.11-0.13 cm³/g, and pore diameters 4.3-4.4 nm. It confirms that Ni_PS catalyst presented a high anti-

sintering and prevented the agglomeration of nickel particles at high temperature. However, as revealed by XPS results, the main peak, assigned to nickel phyllosilicate at around 857.6-859 eV disappeared on the catalyst reduced at 700 °C and the peak corresponding to metallic Ni⁰ species was observed at the binding energy 853.1 eV instead. The results suggest that a suitable proportion of metallic nickel and nickel phyllosilicate can enhance the catalytic performances of Ni_PS catalysts in the furfural hydrogenation to FA.

The influence of reaction temperature on the catalytic performances of 30Ni_PS on furfural conversion, FA selectivity, and FA yield are shown in **Figure 4.9**. Furfural conversion significantly increased with increasing reaction temperature and with increasing reaction time. The complete conversion of furfural (100%) was achieved at 100 °C. At 3 h reaction time, the furfural conversion was enhanced from 44% to 66% and reached 100% when the reaction temperature rose from 50 °C to 80 °C and 100 °C, respectively. The reaction temperature also had a significant impact on the product distribution. From the results, it is obviously seen that higher temperature and longer reaction times promoted deeper hydrogenation of the furan ring in furfural, resulting in higher selectivity towards THFA and lower FA selectivity. The optimum reaction temperature and reaction time to produce the highest yield of FA over the 30Ni-PS catalyst were 80°C and 4 h reaction time, which gave 82% conversion and 42% yield of FA.

Figure 4. 9 Hydrogenation of furfural to FA under different reaction temperature over 30Ni_PS catalysts. Reaction conditions: 250 mg catalyst, 3 mmol furfural, 50 ml methanol solvent, 0.4 mmol dodecane, 20 bar H₂ pressure, reaction time 5 h and catalysts were reduced at 500 °C

4.4 Conclusions

Spherical silica supported nickel phyllosilicate catalysts were synthesized by the one-step modified spherical silica synthesis at room temperature with nickel loadings of 2-30 wt% and evaluated in the liquid-phase selective hydrogenation of furfural to FA at 50 °C and 2 MPa H₂. The unique properties of nickel phyllosilicate were successfully obtained via a simple one-step synthesis strategy by an alternate addition of the nickel and silica sources during the spherical silica synthesis, yielding a high dispersion of small Ni particles (< 3 nm) in the silica matrix, as well as nickel phyllosilicate species throughout the spherical particles, as revealed by TEM and XPS results. The strong interaction between nickel and the silica support and the unique structure of nickel phyllosilicate not only prevent Ni agglomeration during reaction and re-reduction but also facilitate furfural adsorption via the C=O bond through oxygen atoms, resulting in higher FA yield and good recyclability. The nickel phyllosilicate catalysts were superior to the impregnated Ni on spherical silica, which suffered from agglomeration of nickel particles and a large portion of inactive NiO. Moreover, there appeared to be a synergistic effect due to the presence of both metallic nickel and nickel phyllosilicate that promoted FA formation under the reaction conditions used. The optimum reduction temperature, reaction temperature, and reaction time to produce the highest yield of FA (42%) over the nickel phyllosilicate catalyst with 30 wt% Ni were 500 °C, 80 °C, and 4 h reaction time, respectively. The attractive properties of Ni_PS catalysts could be a great potential for mild reaction condition of furfural hydrogenation to FA.

4.5 Materials and methods

4.5.1 Preparation of spherical silica

The spherical silica supports were prepared by using tetraethoxysilane (TEOS) as the silica source and hexadecyltrimethylammonium bromide (CTAB) as the structure-directing agent. The molar ratio of TEOS: CTAB: NH_3 : ethanol: H_2O was 1:0.3:11:58:114. First, a mixture of ethanol and distilled water was stirred at room temperature followed by the addition of aqueous ammonia. After that CTAB was dissolved the mixed solution under continuous stirring for 15 min, TEOS was added and the mixed solution was further stirred for 2 h. Then, the obtained white precipitate was collected by filtration and washed with distilled water. Finally, the resulting powder was dried overnight at 110 °C and calcined at 550 °C for 6 h in air with a heating rate of 2 °C/min

4.5.2 Loading of nickel on spherical silica

Nickel nitrate hexahydrate was chosen as the nickel precursor and was incorporated into the spherical silica support by a one-step modified spherical silica synthesis method with different nickel loadings in the range of 2-30 wt%. After a solution of ethanol, aqueous ammonia, distilled water and CTAB was continuously stirred for 15 min, the nickel precursor and TEOS were simultaneously loaded into the solution and further stirred for 2 h. The precipitate was separated by filtration, washed with distilled water, dried at 110 °C, and calcined at 550 °C for 6 h in air. The obtained catalysts are referred to xNi_PS catalysts, where x indicates the percent nickel loading.

For comparison proposes, 20 wt% Ni on spherical silica was prepared by incipient wetness impregnation and is denoted as the 20Ni_Imp catalyst. The spherical silica support was impregnated with an aqueous solution of nickel precursor followed by drying at 110 °C overnight and calcination in air at 550 °C for 6 h.

4.5.3 Catalytic Reactions

The obtained catalysts were used in the liquid phase hydrogenation of furfural in a 160 mL stainless steel Parr autoclave reactor with a Teflon liner. Prior to the reaction, the catalysts were reduced under H₂ flow at 500 °C for 3 h, then cooled to room temperature, followed by passivation with 1%O₂/N₂ for 1 h. This passivation step was performed to protect and control the reduced catalysts from oxidation in air by creating an oxide layer over the metallic surface. In a typical experiment, 3 mmol of furfural, 50 mL of methanol solvent, 0.25 g of the reduced/passivated catalysts, and 0.4 mmol of dodecane (internal standard) were charged into the autoclave. After that, it was purged with N₂ (300 psig, 2 min) five times and heated to reaction temperature (50-100 °C) under N₂ to ensure minimal reaction during heat up. When the reaction reached the target temperature, the autoclave reactor was purged with H₂ (500 psig, 2 min) five times and the reaction was carried out under 800 rpm stirring with 20 bar of H₂ for 5 h. Samples were collected through a sampling port with a sample volume less than 300 μL for each sample (every 60 min), to minimize reaction volume losses. The liquid products were filtered and analyzed by a Shimadzu GC-2010 chromatograph using an auto sampler with a CP-Wax 58 FFAP CB column and a flame ionization detector. Furfural conversion, selectivity, and FA yield were calculated using dodecane as an internal standard. For the recyclability study, the catalysts were washed with methanol solvent several times and recycled for three cycles under the same reaction conditions.

4.5.4 Catalyst Characterization

X-ray diffraction (XRD) was conducted by using PaNalytical X'Pert Pro Alpha-1 diffractometer with Cu K α radiation. XRD patterns of the calcined and reduced/passivated catalysts were measured in a range from 10° to 90° at room

temperature. Nitrogen physisorption was carried out by a Micromeritics Tristar II 3020 at $-196\text{ }^{\circ}\text{C}$. The samples (about 0.1 g) were pretreated at $180\text{ }^{\circ}\text{C}$ for 10 h under vacuum prior to the nitrogen physisorption measurement. The average pore diameter and pore volume were determined using desorption isotherm by the BJH method. X-ray photoelectron spectroscopy (XPS) analysis was performed on the calcined and reduced/passivated catalysts in a Thermo K-Alpha spectrometer with a monochromatic Al K α radiation source. H_2 -temperature programmed reduction (H_2 -TPR) and CO-pulse chemisorption were carried out on a Micromeritics AutoChem II 2920 equipped with a TCD to measure the reducibility and chemisorption uptake of the catalysts. For TPR experiments, the sample (0.03 g) was loaded on a bed of quartz wool in a quartz u-tube. First, the sample was pretreated under He flow at $200\text{ }^{\circ}\text{C}$ for 1 h and was then cooled to $50\text{ }^{\circ}\text{C}$. The gas was switched to 10% H_2 /Ar flowing at 20 mL/min and the sample was heated to $800\text{ }^{\circ}\text{C}$ at a ramp rate of $10\text{ }^{\circ}\text{C}/\text{min}$. For CO-pulse chemisorption analysis, approximately 0.03 g of the catalyst was introduced into a quartz u-tube like the TPR experiment. Prior to the chemisorption, the catalyst was reduced under H_2 flow at $500\text{ }^{\circ}\text{C}$ for 3 h and was then cooled to $400\text{ }^{\circ}\text{C}$ with He flow for 30 min to remove weakly adsorbed species. After that, the sample was cooled to $40\text{ }^{\circ}\text{C}$ followed by CO-pulse chemisorption testing. Doses of 10%CO/He were passed over the reduced catalyst until saturation was obtained, as analyzed in the TCD. Finally, He was passed over the sample for 60 min. Scanning transmission electron microscopy (STEM) images and EDS element mapping were obtained on a Hitachi HD 2700. TEM samples were dispersed in ethanol and then the suspension was dropped on a TEM grid.

CHAPTER V

CONCLUSIONS

5.1 Conclusions

The spherical silica derived nickel phyllosilicate catalysts were successfully synthesized via a simple one-step modified spherical silica synthesis at room temperature by the direct incorporation of nickel precursor during spherical silica synthesis. The prepared catalysts exhibited a stronger interaction between nickel and silica in the form of nickel phyllosilicate than the silica supported NiO prepared by two step conventional impregnation method. The presence of unique layer structure of nickel phyllosilicate not only solved the main problem of conventional Ni/SiO₂ catalysts during reduction, reaction and regeneration but also can improve the catalytic performances in both gas phase and liquid phase reactions.

Paper I: Highly active and stable Ni-incorporated spherical silica catalysts for CO₂ methanation

Spherical silica supported nickel phyllosilicate catalysts (10 wt%) were synthesized by the one step modified spherical silica synthesis with different loading sequenced of nickel and silica source (Si1_Ni2, Ni1_Si2, and Ni_Alt_Si) and evaluated in gas phase hydrogenation of carbon dioxide. All the nickel loading by one step strategy exhibited nickel phyllosilicate species with a strong interaction between nickel species and silica material and high specific surface area. Ni-doped spherical silica had a spherical silica shape with 350-600 nm and were cover by nickel phyllosilicate layer with the fibrous morphology. The loading sequence of Si and Ni source affect to the formation of nickel phyllosilicate. The layer of nickel phyllosilicate was more apparent on Si1_Ni2 catalyst and showed larger surface area than Ni1_Si2 and Ni_Alt_Si catalysts because the most of nickel species were formed on the surface for Si1_Ni2 and can form inside the pored for Ni1_Si2 and Ni_Alt_Si. For the impregnation catalyst, the

nickel oxide species were observed and the agglomeration of large nickel particles were found on the outer surface.

The amount of CO₂ adsorbed on the nickel phyllosilicate was larger than on the impregnation catalyst, indicating a larger number of active centers on the surface. Thus, all the spherical silica derived nickel phyllosilicates exhibited superior performance than spherical supported NiO prepared by conventional impregnation method in the order: Ni_Alt_Si (~51 %) > Ni1_Si2 (~49%) > Si1_Ni2 (~30 %) > Ni/SSP (Imp) (~10%) with methane selectivity of 80-95% at 350°C. The best CO₂ methanation performances were obtained on the Ni_Alt_Si catalyst (highest CO₂ methanation activity and methane selectivity) due to high electron density of Ni on the surface, high metal dispersion, and high CO₂ adsorption ability. The Ni_Alt_Si catalyst was stable during the regeneration and recyclability tests.

Paper II: Highly stable nickel phyllosilicate prepared by modified spherical silica synthesis in selective hydrogenation of furfural to furfuryl alcohol

Nickel phyllosilicate supported on spherical silica prepared via one-step strategy with various nickel loadings in the 2-30wt% range by an alternate addition of the nickel and silica sources during the spherical silica synthesis and evaluated in liquid phase selective hydrogenation of furfural to furfuryl alcohol. A fibrous-like structure of nickel phyllosilicate was obtained for all the prepared catalysts. After reduction at 500°C, the co-existence of nickel phyllosilicate and nickel metal were observed on the reduced Ni_PS and small nickel particles were highly dispersed without any large aggregation. The crystalline nickel oxide species appeared to be totally reduced into metallic nickel on the 20Ni_Imp. Moreover, all the reduced Ni_PS catalysts still exhibit more than 80% $\text{Ni}^0 + \text{Ni}_{\text{phyllosilicate}} / \text{Ni}_{\text{total}}$ species on the surface, whereas a large portion of Ni oxide species (> 55%) is presented on the impregnated catalyst.

All the nickel phyllosilicate catalysts exhibited higher FA selectivity (65-75%) than 20Ni_Imp (~ 48% FA, producing the highest %THFA). Increasing the Ni loading on Ni_PS to 30 wt% can further increase the furfural conversion without any change in FA selectivity. For similar nickel loading, 20Ni_PS (78% Ni phyllosilicate species, 5% Ni⁰) showed lower activity with higher FA selectivity than 20Ni_Imp because the hydrogenation activity of Ni phyllosilicate is lower than metallic Ni⁰. Thus, Ni²⁺ species that are strongly interacting with SiO₂ can play an important role in binding and activating the C=O group in the furfural structure. The presence of both metallic Ni⁰ and Ni_{phyllosilicate} also produced a synergistic promotional effect for FA formation under mild reaction condition.

The 30Ni_PS exhibited excellent recyclability for furfural hydrogenation with enhanced FA selectivity (from 64% to 74% in the third cycle). The Ni²⁺ species in nickel phyllosilicate catalysts are active and highly stable during reduction, reaction, and regeneration, yielding stable catalytic performances for multiple recycle runs in the furfural hydrogenation to furfuryl alcohol. The 20Ni_Imp catalyst showed poor reusability because the agglomeration of Ni particles on the silica support occurred on 20Ni_Imp as a result from weaker interaction between nickel and the silica support. It can conclude that the fibrous nickel phyllosilicate structure can inhibit the growth of nickel particles and prevent the sintering/leaching of nickel particles because there were no significant changes in the morphology and average nickel particle size of the spent 30Ni_PS catalyst. Thus, the excellence of stability/recyclability of Ni_PS catalysts was ascribed to a unique properties of Ni phyllosilicate that the unreduced Ni²⁺ could serve as a good support for the Ni⁰ species, resulting in the active metallic nickel highly dispersed with strong metal-support interaction.

The highest furfural conversion and FA selectivity were obtained on the reduction temperatures between 500–600 °C. The high reduction temperatures (500,

600, and 700 °C) maintained their high selectivity to FA, varying from 60-70%. Combined reaction results with characterization, the reduction temperature has little effect on the particle size of metallic nickel (3 nm) and there were no major differences in the structural properties of the reduced catalysts. Thus, one step strategy derived nickel phyllosilicate catalyst presented a high anti-sintering and prevented the agglomeration of nickel particles at high temperature. The best catalytic performance was obtained on reduction temperature at 500°C.

The reaction temperature also had a significant impact on the product distribution. The higher temperature and longer reaction times promoted deeper hydrogenation of the furan ring in furfural, resulting in higher selectivity towards THFA and lower FA selectivity. The optimum reduction temperature, reaction temperature, and reaction time to produce the highest yield of FA (42%) over the nickel phyllosilicate catalyst with 30 wt% Ni were 500 °C, 80 °C, and 4 h reaction time, respectively

5.2 Recommendations

1. The acidity analysis should be carried out in order to study the effect of acidity on nickel phyllosilicate.
2. The catalytic performance of selective hydrogenation of furfural to furfuryl alcohol should be investigated at higher temperature (>100 °C) and high hydrogen pressure comparable to the other reports.

*Reaction conditions: 50 μ l FA in 10 ml water at 50 °C with a 50 mg catalyst under 20 bar H₂

APPENDIX B

Table B1 Hydrogenation of furfural to FA under methanol solvent over 10wt% Ni by one-step modified spherical silica synthesis with alternate addition of the nickel and silica sources during the spherical silica synthesis modified with second metal.

| Catalysts | conversion | Selectivity (%) | | | | | FA Yield (%) |
|------------|------------|-----------------|------|-----|-------|--------|--------------|
| | | FA | THFA | SP | Furun | Others | |
| No cat | 36 | | | 100 | | | 0 |
| NiAltSi | 81 | 73 | 14 | | | 13 | 59 |
| Fe-NiAltSi | 64 | 70 | 8 | | | 22 | 45 |
| Mn-NiAltSi | 79 | 48 | 12 | | | 40 | 38 |
| Pd-NiAltSi | 76 | 7 | 83 | | 3 | 7 | 5 |
| Co-NiAltSi | 91 | 34 | | | 55 | 11 | 31 |

*Reaction conditions: 50 μ l FA in 10 ml methanol at 50 °C with a 50 mg catalyst under 20 bar H₂ for 2 h, Catalysts: 10wt%Ni and Ni : 2nd metal mole ratio = 15:1

*solvent product (SP) = 2-furaldehyde dimethyl acetal

Table B2 and figure B1 CO₂ conversion and CH₄ selectivity over 10wt% Ni by one-step modified spherical silica synthesis with alternate addition of the nickel and silica sources during the spherical silica synthesis modified with second metal.

| Catalysts | Temp (°C) | Time (min) | CO ₂ conversion | CH ₄ selectivity |
|--------------|-----------|------------|----------------------------|-----------------------------|
| Ni_Alt_Si | 300 | 60 | 20.8 | 100 |
| | 450 | 60 | 94.1 | 100 |
| Fe-Ni_Alt_Si | 300 | 60 | 23.78 | 100 |
| | 450 | 60 | 97.16 | 100 |
| Mn-Ni_Alt_Si | 300 | 60 | 23.72 | 100 |
| | 450 | 60 | 92.73 | 100 |
| Co-Ni_Alt_Si | 300 | 60 | 28.02 | 100 |
| | 450 | 60 | 97.92 | 100 |
| Pd-Ni_Alt_Si | 300 | 60 | 24.5 | 100 |
| | 450 | 60 | 96.29 | 100 |

**Reaction conditions: reduced under H₂ at 500°C 3 h, Catalyst = 0.1 g, WHSV = 24000 cm³/g_{cat}h, H₂:CO₂ = 10:1, Catalysts: 10wt%Ni and Ni : 2nd metal mole ratio = 15:1

APPENDIX C

The effect of second metal, preparation method and loading sequence of Ni, Si, and second metal were investigated in hydrogenation of furfural to FA

Catalysts: 20wt%Ni loading, Ni:Fe mole ratio 10:1, Ni:Cu mole ratio 10:1 and 5:1

NiAltSi = One-step modified spherical silica synthesis with alternate addition of the nickel and silica sources during the spherical silica synthesis

(2CuNiSi)Alt = One-step modified spherical silica synthesis with alternate addition of the nickel, copper and silica sources during the spherical silica synthesis (Ni:Cu mole ratio 10:1)

(4CuNiSi)Alt = One-step modified spherical silica synthesis with alternate addition of the nickel, copper and silica sources during the spherical silica synthesis (Ni:Cu mole ratio 5:1)

(NiAltSi)-4Cu = One-step modified spherical silica synthesis with alternate addition of the nickel and silica sources during the spherical silica synthesis and then addition of copper (Ni:Cu mole ratio 5:1)

(NiCu)-Imp/SSP = Impregnation co-precursor between nickel and copper source onto spherical silica (Ni:Cu mole ratio 10:1)

NiFeSi = One-step modified spherical silica synthesis with alternate addition of the nickel, iron and silica sources during the spherical silica synthesis (Ni:Cu mole ratio 10:1)

(NiSi)-Fe = One-step modified spherical silica synthesis with alternate addition of the nickel and silica sources during the spherical silica synthesis and then addition of iron (Ni:Cu mole ratio 10:1)

*Reaction conditions: 250 mg catalyst, 3 mmol furfural, 50 ml methanol solvent, 0.4 mmol dodecane, reaction temperature 80 °C, 20 bar H₂ pressure, reaction time 5 h and catalysts were reduced at 500 °C

จุฬาลงกรณ์มหาวิทยาลัย
CHULALONGKORN UNIVERSITY

VITA

NAME Sasithorn Kuhaudomlap

DATE OF BIRTH 6 April 1991

PLACE OF BIRTH Kanchanaburi

INSTITUTIONS ATTENDED Bachelor's Degree: Chemical Engineering from Department of Chemical Engineering, Faculty of Engineering and Industrial Technology, Silpakorn University, Nakhonpathom, Thailand
Master's Degree: Chemical Engineering at Department of Chemical Engineering, Chulalongkorn University, Bangkok Thailand
Doctoral Degree: Chemical Engineering at Department of Chemical Engineering, Chulalongkorn University, Bangkok Thailand

HOME ADDRESS 15/3 Moo 3 Tombon Thamai
Amphoe Thamaka
Changwat Kanchanaburi
71120

PUBLICATION Publications:

- Sasithorn Kuhaudomlap, Okorn Mekasuwandumrong, Piyasan Praserthdam, Shin-Ichiro Fujita, Masahiko Arai and Joongjai Panpranot, "The H₂-treated TiO₂ supported Pt catalysts prepared by strong electrostatic adsorption for liquid-phase selective hydrogenation", Catalysts 2018, 8, 87.
- Sasithorn Kuhaudomlap, Piyasan Praserthdam, Masayuki Shirai, Joongjai Panpranot. "Highly active and stable Ni-incorporated spherical silica catalysts for

CO₂methanation” *Catalysis Today*. 2020, 358, 30-36.

Conferences:

- Sasithorn Kuhaudomlap, Okorn Mekasuwandumrong, Piyasan Praserthdam and Joongjai Panpranot “Ni-doped high surface area spherical silica catalysts for CO₂ methanation” The 8th Tokyo Conference on Advanced Catalytic Science and Technology (TOCAT8), August 5 - 10, 2018 at Yokohama, Japan (Oral presentation).
- Sasithorn Kuhaudomlap, Piyasan Praserthdam, Masayuki Shirai, and Joongjai Panpranot “Highly active and stable Ni-incorporated spherical silica catalysts for CO₂ methanation” 3rd International Conference on Catalysis and Chemical Engineering 2019 (CCE-2019), February 25 – 27, 2019 at Houston, TX, United States (Oral presentation).
- Sasithorn Kuhaudomlap and Joongjai Panpranot “Selective hydrogenation of furfural to furfuryl alcohol over nickel phyllosilicate catalyst” The 2021 National RGJ and RRI Conference, 14 June 2021, Online. (Poster Presentation)

Short-term research:

The Georgia Institute of Technology, the school of Chemical & Biomolecular Engineering, Atlanta, Georgia, U.S.A., under supervision of Professor Christopher W. Jones.
