# # 5372460523: MAJOR PETROCHEMISTRY AND POLYMER SCIENCE

KEYWORDS: CHITOSAN/ MUCOADHESIVE/ THIOLATED- CHITOSAN

MULLIKA KONGSONG: SYNTHESIS AND PROPERTIES OF MUCOADHESIVE THIOLATED CHITOSAN FOR SIMVASTATIN DELIVERY SYSTEM. ADVISOR: ASSOC. PROF. POLKIT SANGVANICH, Ph.D., 111 pp.

The objective of this research was to prepare a mucoadhesive thiolated chitosan suitable for delivery of hydrophobic drugs. This can be achieved by modification of chitosan with 5-amino-2-mercaptobenzimidazole (MBI) using methyl acrylate (MA) as a linker agent. The substitution of MA was about 14.38% calculated by  $^1\text{H}$  NMR. The amounts of thiol groups (MBI) and disulfide bonds coupled on MA-CS determined by Ellman's method were 11.86 and 6.54  $\mu\text{mol}$  per gram of polymer, respectively. Periodic acid: schiff (PAS) colorimetric method was used to study mucin-conjugated polymer bioadhesive strength in the simulated gastrointestinal fluid (pH 1.2, 4.0 and 6.4). The MA-CS and MBI-MA-CS showed stronger mucoadhesive property 10.28 and 11-fold, respectively than that of unmodified chitosan at pH 1.2. Additionally, the applications of CS and modified CS as hydrophobic drug delivery carriers were investigated using simvastatin (SV) as a model drug. The microspheres of CS and modified CS were fabricated using electrospray ionization technique. The swollen particle sizes of microspheres were in the range of 1-5  $\mu\text{m}$  measured by particle sizer. The SV loaded microspheres exhibited over 80% drug entrapment efficiency. The mucoadhesiveness of SV-MA-CS and SV-MBI-MA-CS microspheres displayed 7- and 7.33-fold at pH 1.2, respectively compared to SV-CS. The obtained microspheres not only reduced the burst effect but also prolonged release of SV as long as 12 h.

## ACKNOWLEDGEMENTS

The author thanks many people for kindly providing the knowledge of this study. First, I would like to express gratitude and appreciation to my advisor, Associate Professor Dr. Polkit Sanvanich and co-advisor, Associate Professor Dr. Nongnuj Muangsin for invaluable guidance and suggestions throughout this work.

I wish to express my grateful thank to Dr. Krisana Siraleartmukul for her valuable advice. Furthermore, the author also thank the Center for Petroleum, Petrochemicals and Advanced Materials, Chulalongkorn University, Bangkok 10330, Thailand and the centre of Chitin-Chitosan Biomaterial, Metallurgy and Materials Science Research Institute of Chulalongkorn University for providing the equipment, chemicals, and facilities. I thank the National Nanotechnology Center (NANOTEC) for facilitating the Zetasizer Nano ZS for a particle size measurement

I would also like to thank Asssistant Professor Dr. Warinthorn Chavasiri, Associate Professor Dr. Voravee Hoven and Asssistant Professor Dr. Nalena Praphairaksit attending as the chairman and members of my thesis committee, respectively, for their kind guidance and valuable suggestions and comments.

Finally, I would like to express thanks to my family for their care and supports to make my study successful. Thank to friends for their help, cheerful, endless love, understanding and encouragement.

# CHAPTER I

## INTRODUCTION

### 1.1 Introduction

Simvastatin (SV) is a synthetic derivative of a fermentation product of *Aspergillus terreus*, and marketed under the trade name of Zocor. It is widely used for the treatment of primary hypercholesterolemia and coronary heart disease. After oral administration, Simvastatin (a lactone) (Figure 1.1) undergoes hydrolysis and is converted to its  $\beta$ ,  $\delta$ -dihydroxy acid form (simvastatin acid) by the cytochrome-3A system in liver, where it is a potent competitive inhibitor of 3-hydroxyglutaryl-CoA reductase the enzyme that catalyzes the rate-limiting step of cholesterol biosynthesis [1]. This leads to up-regulation of low-density lipoprotein (LDL) receptors and an increase in catabolism of LDL cholesterol.

Simvastatin is practically insoluble in water with solubility of 30  $\mu\text{g/mL}$  [2], short biological half-life (3 hours), high first-pass metabolism and poorly absorbed from the gastrointestinal (GI) tract (<5%) [3]. The past years, development mucoadhesive buccal tablets of SV using mucoadhesive polymers found that the polymer retarded the release of simvastatin and the absorption of SV improved [4].

**Figure 1.1** Chemical structure of simvastatin.

Mucoadhesive polymers are synthetic or natural macromolecules which are capable of attaching to mucosal surfaces. The concept of mucoadhesive polymers has been introduced into the pharmaceutical application [5]. Over the past few years, mucoadhesive polymers have received attention as excipients for various drug delivery systems due to the possibility of drug localization at the target site, a prolonged residence time at the site of drug absorption that shows sustained release of drug there. The drugs that are absorbed through the mucosal lining of tissues can enter directly into the blood stream and not be inactivated by enzymatic degradation in the gastrointestinal tract and an increase in drug concentration gradient on the mucosa, as a result, the bio-availability of drug can be improved [6-8]. Due to these advantages, many attempts have been made to improve the mucoadhesive properties of polymeric carriers.

The design and selection of polymers for drug delivery is partially based on the concept that mucoadhesive polymers should have functional groups, which can be summarized as follows:

- 1) Carboxyl (-COOH) and hydroxyl (-OH), hydrogen-bonding group
- 2) Hydroxyl (-OH) and amide (-NH<sub>2</sub>) groups, or strong anionic or positive charges
- 3) Sufficient chain flexibility.
- 4) High molecular weight

These polymers would be able to interact more strongly to the mucus glycol-proteins [9, 10].

Chitosan or poly [ $\beta$ -(1-4)-2-amino-2-deoxy-d-glucopyranose] (Figure 1.2b) is a cationic natural linear polysaccharide consisting of copolymers of glucosamine and N-acetylglucosamine. It is obtained by deacetylation of chitin (Figure 1.2a), which present in outer structure in marine crustaceans such as crabs and shrimp. Chitosan is soluble in dilute acidic solutions below pH 6.0 due to the quaternisation of the amine groups that have a pKa value of 6.3 making chitosan promotes

solubility, whereas chitosan is insoluble at alkaline and neutral pH. The primary amino group accounts for the possibility of relatively easy chemical modification of chitosan and salt formation with acids.

Chitosan used for developing mucoadhesive polymer due to its non-toxic, high biocompatible and enzymatic biodegradable [11]. The presence of -OH and -NH<sub>2</sub> groups, together with cationic property of chitosan are considered to be responsible via non-covalent bonds e.g. hydrogen bonds and ionic interactions with sialic groups of the mucus layer, resulting in a good mucoadhesive property. Therefore, chitosan considered to be suitable for application in pharmaceutical technology such as drug delivery and gene delivery carriers [12], wound healing accelerators and tissue engineering scaffolds [13].

(a) Chitin

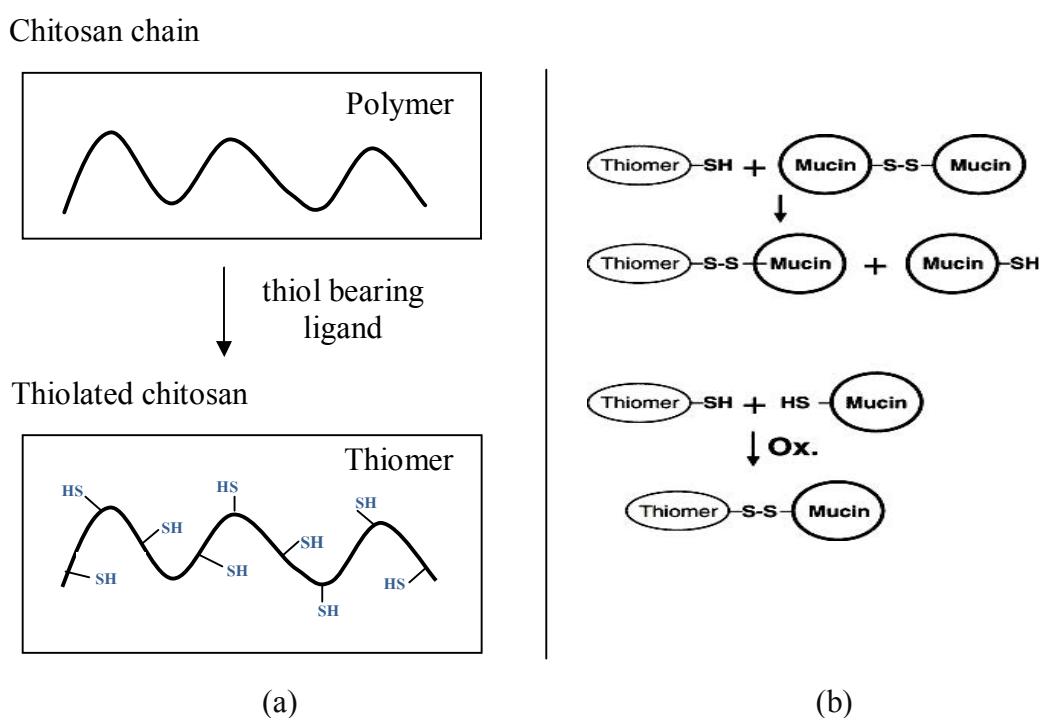

(b) Chitosan

**Figure 1.2** Structures of a) chitin and b) chitosan

Recently, these mucoadhesive properties can be enhanced with introducing thiol groups on chitosan so called for thioimer/thiolated chitosan (Figure 1.3a) [14]. Some research, such as chitosan–thioglycolic acid conjugates (chitosan-TGA) [15],

chitosan-N-acetyl cysteine [16] and chitosan-homocysteine thiolactone (HT-chitosan) [17] are strongly improved in comparison to the unmodified chitosan. Mucoadhesive properties of thiolated chitosans are explained by the formation of covalent bonds between thiol groups of the polymer and cysteine rich sub-domains of mucus glycoproteins layer via thio/disulfide exchange reaction and an oxidation process (Figure 1.3b) [18]. These covalent bonds are stronger than the non-covalent bonds.

**Figure 1.3** Structures of (a) thiolated chitosan and (b) mechanism of disulfide bond formation between thiomer and mucus glycoproteins (mucin)

However, the poor interaction of these thiolated polymers with hydrophobic drug molecules often resulted in a faster drug release, which will affect their potential applications in pharmaceutical fields [19].

The aim of this study was to attempt synthesize a mucoadhesive thiolated chitosan suitable for delivery of simvastatin (as a model hydrophobic drugs). These mucoadhesive thiolated chitosan designed in order to increase hydrophobicity. This

can be performed by (i) increase the length of the grafted chain, (ii) coupling an aromatic system into the chitosan backbone to increase the stacking with the hydrophobic drugs and finally, (iii) introducing the thiol group to form chemical bond with thiol group in mucus membrane. This can be achieved by modification of chitosan with 5-amino-2-mercaptobenzimidazole (MBI) using methyl acrylate (MA) as a linker agent (Figure 1.4). The amount of thiol groups immobilized on chitosan was determined by Ellman's method, Periodic acid: Schiff (PAS) colorimetric method was used to qualify mucin-conjugated polymer bioadhesed strength in the simulated gastrointestinal fluid (pH 1.2, 4.0 and 6.4).

**Figure 1.4** Synthesis scheme of *N*-carboxyethyl chitosan methyl ester (MA-CS) and MBI-*N*-carboxyethyl chitosan methyl ester (MBI-MA-CS)

Various methods have been used to prepare chitosan particulate systems such as ionic gelation, coacervation/precipitation, emulsion cross-linking [12] and ultrasonification [20] are summarized in Table 1.1. The disadvantages of microspheres is difficult to control the particle sizes and widely size distribution, the droplet easily agglomerate. This disadvantage will bring some limitations in application: (1) the reproducibility of microspheres is poor among batches, which will result in poor repeatability of the release behavior and efficacy of drug among doses; (2) the bioavailability of drug will be low if the size distribution of microsphere is broad. And, the side-effects of the drug will be increased. Therefore, it is necessary to prepare uniform-sized microspheres and control the size of microspheres for their applications in drug delivery system.

Table 1.1 Chitosan- based drug delivery systems prepared by different methods [12]

Type of system	Method of preparation
Microspheres	Emulsion cross-linking, Coacervation/precipitation Spray-drying, Ionic gelation
Nanoparticles	Emulsion-droplet coalescence Coacervation/precipitation

One of the novel and attractive technique has been applied to generate nanoparticles is known as electro spraying ionization technique (Figure 1.5) is a method of liquid atomization using electrostatic forces. The polymer flowing out of the nozzle in the form of droplet when applied high voltage potential forces. The advantages of this technique are simplicity and unique one-step technique [21]. It's able to obtain uniform particle size, narrow size distribution can be produced under easily controlled conditions [22], such as the flow rate, voltage applied to the nozzle and working distance. Electro spraying technique suitable for use in drug delivery systems as well as many other applications such as encapsulate various materials (biomacromolecules, microparticles and living cells) within the microcapsules [23].

**Figure 1.5** The droplet is generated by electrical force

Therefore, the present work was to prepare controlled release microspheres of SV, using CS and modified chitosan (MA-CS and MBI-MA-CS) as the retarding material, by application of electro-spray ionization technique (Figure 1.6) and study the *In vitro* release behavior of the spheres in simulated gastrointestinal fluid pH 1.2, 4.0 and 6.4

**Figure 1.6** Scheme of drugs loaded mucoadhesive microspheres

## 1.2 The objectives of this research

- 1) Modify chitosan to improve mucoadhesive properties suitable for hydrophobic drugs delivery.
- 2) Preparation of chitosan and modified chitosan solid micro/nanoparticles with electro-spray technique.

### 1.3 The scope of research

The scope of this research was carried out by stepwise methodology as follows:

- 1) Review literature for related research work.
- 2) **Part I** : Modifying chitosan
  - a. Preparation of thiolated chitosan (MA-CS, MBI-MA-CS)
  - b. Characterization of the physical and chemical properties of chitosan and modified chitosan using FTIR, <sup>1</sup>H-NMR, <sup>13</sup>C-NMR, TGA.
  - c. Determination degree of MA substitution.
  - d. Determination degree of thiol and disulfide substitution.
  - e. *In vitro* investigation of mucoadhesive property in simulated gastric fluid (SGF) pH 1.2 and 4.0 and the simulated intestinal fluid (SIF) pH 6.4 by using UV-Vis method
  - f. swelling properties in pH 1.2, 4.0 and 6.4.
  - g. Toxicity study of chitosan and modified chitosan.

**Part II** : Fabrication and evaluation of the modified chitosan and chitosan as a drug delivery carrier

- a. Preparation of the microspheres with and without drug
  - b. Characterization of the obtained microspheres in terms of morphology, size and size distribution, zeta potential, chemical analysis and thermal behavior.
  - c. Determination of the drug encapsulation efficiency
  - d. Study the *In vitro* release behavior of the spheres in simulated gastrointestinal fluid pH 1.2, 4.0 and 6.4 using UV-Vis method.
- 3) Report, Discussion and Writing up thesis.

**Part I:** Flow chart for synthesis and characteristic

**Part II: Pharmaceutical application****Figure 1.5** Flow chart of research

## CHAPTER II

### THEORY AND LITERATURE REVIEWS

#### 2.1 Hypercholesterolemia and coronary heart disease

Hypercholesterolemia is a condition characterized by very high levels of cholesterol in the blood that result from a combination of genetic (*the APOB, LDLR, LDLRAP1, and PCSK9* genes) and environmental risk factors. Lifestyle choices including diet, exercise, and tobacco smoking strongly influence the amount of cholesterol in the blood. Additional factors that impact cholesterol levels include a person's gender and age. People with hypercholesterolemia have a high risk of developing a form of coronary artery disease. This condition occurs when excess cholesterol in the bloodstream is deposited in the walls of blood vessels (Figure 2.1), particularly in the arteries that supply blood to the heart (coronary arteries).

**Figure 2.1** A gradual build-up of fatty material (called atheroma) within their walls

#### 2.2 Simvastatin

Simvastatin (SV) is a synthetic derivative of a fermentation product of *Aspergillus terreus*, and marketed under the trade name of Zocor. It is a member of the statin class of pharmaceuticals that widely used for Lowering cholesterol and other lipids (fats) in the blood to reduce the risk of heart disease problems but

**Figure 2.3** Pathway of simvastatin

### 2.3 Controlled released system

In recent years, the study of controlled release of drugs and other bioactive agents from polymeric devices has attracted many researchers from around the world. Controlled drug delivery include both sustained delivery over days/weeks/months/ years and targeted (e.g., to a tumor, diseased blood vessel, etc.) delivery on a one-time or sustained basis. Controlled release formulations can be used to reduce the amount of drug necessary to cause the same therapeutic effect in patients. The convenience of fewer and more effective doses also increases patient compliance [26].

Controlled release over an extended duration is highly beneficial for drugs that are rapidly metabolized and eliminated from the body after administration [27]. An example of this benefit is shown schematically in Figure 2.4 in which the concentration of drug at the site of activity within the body is compared after

immediate release from 4 injections administered at 6 hourly intervals and after extended release from a controlled release system. Drug concentrations may fluctuate widely during the 24 h period when the drug is administered via bolus injection, and for only a portion of the treatment period is the drug concentration in the therapeutic window (i.e., the drug concentration that produces beneficial effects without harmful side effects). With the controlled release system, the rate of drug release matches the rate of drug elimination and, therefore, the drug concentration is within the therapeutic window for the vast majority of the 24 h period.

**Figure 2.4** Drug concentrations at site of therapeutic action after delivery as a conventional injection (thin line) and as a temporal controlled release system (bold line) [27].

Controlled drug delivery occurs when a polymer is combined with the drug or other active agent in such a way that the active agent is released from the material in a predesigned manner [28].

**Figure 2.5** Representation of controlled release systems

a) reservoir and b) matrix devices [28].

### 2.3.1 Controlled-release mechanisms

There are three primary mechanisms by which active agents can be released from a delivery system [29].

1. Diffusion-controlled delivery systems
2. Swelling-controlled delivery systems
3. Degradation-controlled delivery systems

Any or all of these mechanisms may occur in a given release system. Diffusion occurs when a drug or other active agent passes through the polymer that forms the controlled-release device. *The diffusion* can occur through pores in the polymer matrix, by passing between polymer chains. Examples of diffusion-release systems are shown in Figures 2.5

**Figure 2.6** Drug delivery from a typical matrix drug delivery system

In Figure 2.5, a polymer and active agent have been mixed to form a homogeneous system, also referred to as a matrix system. Diffusion occurs when the drug passes from the polymer matrix into the external environment. As the release continues, its rate normally decreases with this type of system, since the active agent has a progressively longer distance to travel and therefore requires a longer diffusion time to release. For *the swelling* of the carrier increases the aqueous solvent content within the polymer matrix, enabling the drug to diffuse through the swollen network into the external environment. Most of materials used are based on hydrogel. The swelling can be triggered by a change in the environment surrounding such as pH, temperature, ionic strength, etc.

There are two major types of *degradation-controlled release systems*;

- Erodible systems, drug release occurs due to degradation or dissolution of the hydrogel.
- Pendant chain systems, the drug is affixed to the polymer backbone through degradable linkages. As these linkages degrade, the drug is released.

## 2.4 Mucoadhesion/bioadhesive

In the early 1980s, the concept of mucoadhesives, was introduced into the controlled drug delivery area. Mucoadhesives are synthetic or natural polymers that will attach to related tissue or to the surface coating of the tissue for targeting various absorptive mucosa such as ocular, nasal, pulmonary, buccal, vaginal etc [7]. The system of drug delivery is called as mucoadhesive drug delivery system. This system has advantage like [30];

1. Prolongs the residence time of the dosage form at the site of absorption.
2. Due to an increased residence time it enhances absorption and hence the therapeutic efficacy of the drug.
3. Increase in drug bioavailability due to first pass metabolism avoidance.
4. Drug is protected from degradation in the acidic environment in the gastrointestinal tract.
5. Improved patient compliance-ease of drug administration.

### 2.4.1 Mucoadhesive mechanism

Mucus is a complex viscous adherent secretion which is synthesized by specialized goblet cells. Mucus is composed mainly of water (>95%) and mucins, which are glycoproteins of exceptionally high molecular weight. Furthermore, pendant sialic acid and sulphate groups located on the glycoprotein molecules result in mucin behaving as an anionic polyelectrolyte at neutral pH [31]. Other non mucin components of mucus include secretory lysozyme, lactoferrin, lipids, polysaccharides, and various other ionic species [31].

Development of novel mucoadhesive delivery systems are being undertaken so as to understand the various mechanism of mucoadhesion (Figure 2.7) and improved permeation of active agents.

**Figure 2.7** Mechanism of Mucoadhesion

The mechanism of mucoadhesion is generally divided into two steps are shown in Figure 2.8 [30]

**The first stage** (also known as contact stage), the contact between the mucoadhesive polymer and mucous membrane, with spreading and swelling of the formulation, initiating its deep contact with the mucus layer.

**The second stage** (the consolidation stage), the mucoadhesive materials are activated by the presence of moisture. Moisture plasticizes the system, allowing the mucoadhesive molecules to break free and to link up by weak vander Waals and hydrogen bond

**Figure 2.8** The two stages of the mucoadhesion process [32]

## 2.4.2 Mucoadhesion theories

There are six general theories have been proposed which can improve understanding for the phenomena of adhesion and can also be extended to explain the mechanism of bioadhesion. The theories include [30, 33]:

### 2.4.2.1 Electronic Theory

Electronic theory is based on the premise that both mucoadhesive and biological materials possess opposing electrical charges. Thus, when both materials come into contact, they transfer electrons leading to the building of a double electronic layer at the interface, where the attractive forces within this electronic double layer determines the mucoadhesive strength.

### 2.4.2.2 Wetting Theory

The wetting theory applies to liquid systems which present affinity to the surface in order to spread over it. This affinity can be found by using measuring techniques such as the contact angle. The general rule states that the lower the contact angle then the greater the affinity (Figure 2.9).

**Figure 2.9** Schematic diagram showing influence of contact angle between device and mucous membrane on bioadhesion.

### 2.4.2.3. Adsorption Theory

According to the adsorption theory, the mucoadhesive device adheres to the mucus by secondary chemical interactions, such as in van der Waals and hydrogen bonds, electrostatic attraction or hydrophobic interactions. For example, hydrogen bonds are the prevalent interfacial forces in polymers containing carboxyl groups. Such forces have been considered the most important in the adhesive interaction phenomenon because, although they are individually weak, a great number of interactions can result in an intense global adhesion

### 2.4.2.4. Diffusion Theory

This theory assumes the diffusion of the polymer chains, present on the substrate surfaces shown in Figure 2.10, across the adhesive interface thereby forming a networked structure.

**Figure 2.10** Secondary interactions resulting from interdiffusion of polymer chains of bioadhesive device and of mucus.

### 2.4.2.5. Mechanical Theory

Mechanical Theory explains the diffusion of the liquid adhesives into the micro-cracks and irregularities present on the substrate surface thereby forming an interlocked structure which gives rise to adhesion.

#### 2.4.5.6. Cohesive Theory

This theory proposes that the phenomena of bioadhesion are mainly due to the intermolecular interactions amongst like-molecules. However, none of these mechanisms or theories alone can explain the mucoadhesion which occurs in an array of different situations.

### **2.4.3 The mucoadhesive/mucosa interaction**

As mentioned above, bioadhesion may take place either by physical or by chemical interactions. For adhesion to occur, molecules must bond across the interface. These bonds can arise in the following way [32].

#### 2.4.3.1. physical interactions

- Hydrogen bonds

A hydrogen atom, when covalently bonded to electronegative atoms such as oxygen, fluorine or nitrogen, carries a slight positive charge and is therefore attracted to other electronegative atoms. The hydrogen can therefore be thought of as being shared, and the bond formed is generally weaker than ionic or covalent bonds.

- Van-der-Waals bonds

The Van – der – Waals bonds are some of the weakest forms of interaction that arise from dipole–dipole and dipole-induced dipole attractions in polar molecules, and dispersion forces with non-polar substances.

- Hydrophobic bonds

Hydrophobic bonds that occur when non-polar groups are present in an aqueous solution. Water molecules adjacent to non-polar groups form hydrogen bonded structures, which lowers the system entropy. There is therefore an increase in the tendency of non-polar groups to associate with each other to minimise this effect.

### 2.4.3.2. chemical interactions

- Ionic bonds

The interaction between two oppositely charged ions via electrostatic interactions (e.g. in a salt crystal).

- Covalent bonds

Electrons are shared, in pairs, between the bonded atoms in order to “fill” the orbitals in both. These are also strong bonds (e.g. thiomers).

### 2.4.4 Mucoadhesive polymers

Mucoadhesive polymers may provide an important tool to improve the bioavailability of the active agent by improving the residence time at the delivery site. Mucoadhesive polymer have been also used for coating medical devices. As an example a new generation of intestine inspection device has been recently developed in which mucoadhesive polymer coating make intestinal locomotion possible. These materials are natural or synthetic hydrophilic molecules (Table 2.1).

Table 2.1: List of Natural and Synthetic polymers [31]

<b>Synthetic polymers</b>	<b>Natural polymers</b>
Cellulose derivatives	Tragacanth
Polycarbophil	Sodium alginate
Poly acrylic acid	Karaya gum
Poly(vinyl pyrrolidone)	Guar gum
Poly(vinyl alcohol)	Gelatin
Poly(hydroxyethyl methylacrylate)	Chitosan

These polymers can be subdivided into three classes: cationic, anionic and nonionic.

- **Cationic polymers** such as chitosan can interact with the mucus surface, since it is negatively charged at physiological pH.

- **Anionic polymers**, including carboxymethylcellulose and alginates. The alginates, negatively charged polysaccharides, are widely used in the production of microparticles and are frequently reported as polyanionic mucoadhesive polymers. Synthetic polymers derived from poly(acrylic acid)(carbomers) has been considered as a good mucoadhesive material with negatively charged and not water soluble but form viscous gels when hydrated such as polycarbophil.

- **Nonionic polymers**, including hydroxypropylmethylcellulose, hydroxy ethylcellulose and methylcellulose, present weaker mucoadhesion force compared to anionic polymers

The novel mucoadhesive systems such as thiolated polymers are obtained by the addition of conjugated sulfidryl groups increased mucoadhesive properties due to formation of disulfide bridges with cystein domains of glycoproteins of the mucus. An ideal polymer should exhibit the ability to incorporate both hydrophilic and lipophilic drugs. Moreover another study, carried out by Grabovac, Guggi, and Bernkop-Schnürch (2005) established a ranking of the most studied polymers, showing that both thiolated chitosan and polycarbophil are the most mucoadhesive polymer.

#### **2.4.5 Mucoadhesive polymers dosage form**

The primary objectives of mucoadhesive dosage forms are to provide intimate contact of the dosage form with the absorbing surface and to increase the residence time of the dosage form at the absorbing surface to prolong drug action. Mucoadhesive polymers have been utilised in many different dosage forms in efforts to achieve systemic delivery of drugs through the different mucosa in Figure 2.11. These dosage forms include tablets, patches, films, semisolids and powders. To serve as

mucoadhesive polymers, the polymers should possess some general physiochemical features such as predominantly anionic hydrophilicity with numerous hydrogen bond-forming groups, suitable surface property for wetting mucus/mucosal tissue surfaces and sufficient flexibility to penetrate the mucus network or tissue crevices [7]. The mucoadhesive drug delivery system may include the following [34].

1. Gastrointestinal delivery system.
2. Nasal delivery system.
3. Ocular delivery system.
4. Buccal delivery system.
5. Vaginal delivery System.
6. Rectal delivery system.

**Figure 2.11** Some scenarios where mucoadhesion can occur [32].

1. Dry or partially hydrated dosage forms contacting surfaces with substantial mucus layers (e.g. aerosolised particles deposited in the nasal cavity).
2. Fully hydrated dosage forms contacting surfaces with substantial mucus layers (e.g. particle suspensions in the gastrointestinal tract).

3. Dry or partially hydrated dosage forms contacting surfaces with thin/discontinuous mucus layers (e.g. a tablet placed onto the oral mucosa).

4. Fully hydrated dosage forms contacting surfaces with thin/discontinuous mucus layers (e.g. aqueous microparticles administered into the vagina).

## 2.5 **Technique to prepare microparticle** [12]

Various methods have been used to prepare microparticle such as thermal Cross-Linking, Spray Drying, Solvent Evaporation, Emulsification and Iontropic Gelation Technique, Wet Inversion Technique, Complex Coacervation. These method have the disadvantages of microspheres is difficult to control the particle sizes and widely size distribution, the droplet easily agglomerate. This disadvantage will bring some limitations in application:

(1) The reproducibility of microspheres is poor among batches, which will result in poor repeatability of the release behavior and efficacy of drug among doses, and furthermore, it is difficult to investigate the relationship between doses and treatment effects

(2) Because the accumulated location of the microspheres containing drug depends on the size of the particles, the bioavailability of drug will be low if the size distribution of microsphere is broad. And, the side-effects of the drug will be increased [35].

Therefore, it is necessary to prepare uniform-sized microspheres and control the size of microspheres for their applications in drug delivery system.

### *Electrospraying ionization technique*

This technique is the novel an attractive technique has been applied to generate nanoparticles. The principle of electrospraying is based on the theory of charged droplets; stating that an electric field applied to a liquid droplet exiting a capillary is able to deform the interface of the droplet [36]. The electric charge generates an electrostatic force inside the droplet which competes with the surface tension of the droplet, forming the Taylor cone, characteristic of a charged droplet. Eventually, the electrostatic force generated by the use of high voltage on the

capillary that able to overcome the surface tension of the droplet. The excess charge then needs to be dissipated and smaller charged droplets on the micro to nano-scale are ejected from the primary droplet, thus reducing its charge without significantly reducing its mass. Due to Coulomb repulsion of the charges, the droplets disperse well and do not coalesce during their flight toward the collector.

**Figure 2.12** Schematic diagram of the instrumentation for electro spray technique

Several spraying modes [37] can occur during electro spraying that depending on setup geometry (e.g. distance between capillary and plate or capillary radius), volume feed rate, liquid properties (surface tension, electrical conductivity) and applied potential (Figure 2.12).

Firstly: The dripping mode

In the absence of an electric field the liquid flows drop by drop. Increasing the potential from zero increases the droplet dripping frequency and decreases the droplet size.

Secondly: The microdripping mode

The liquid droplet at the capillary exit is deformed by the electric field and takes the shape of a cone. A droplet is formed directly at the droplet apex.

Thirth: The cone jet mode

The cone is extended by a jet which is breaking up into droplets. The shape of the liquid at the capillary exit is alternating between the form of a cone (emitting a jet) and a rounded drop. The most desired being the single cone-jet mode, due to its stability and reproducibility

Fourth: The multi jet and ramified jet mode

At increased potential the cone jet becomes unstable and two or more jets appear. This is the multi jet. The number of jets increases with increasing potential. Simple jet, ramified jet and spindle mode are modes that appear at even higher electric potentials. Here the jets emitted by the capillary are highly charged and unstable.

The advantages of this technique over conventional mechanical spraying systems with droplet charged by induction such as

1. simplicity and unique one-step technique.
2. It's able to obtain uniform particle size, narrow size distribution.

3. Droplet size is smaller than that available from conventional mechanical atomizers and can be smaller than 1 mm.

4. Particle size can be produced under easily controlled conditions such as the flow rate, voltage applied to the nozzle and working distance.

The applications of electrospraying such as, the ceramic coatings, as powder in the cosmetic or pharmaceutical industries, painting of automobiles, toner in electro-reprographic systems. Moreover used electrified masks to deposit silica nanoparticles in geometric micrometer-sized patterns on GaAs substrates. This makes electrosprays interesting for any kind of layer or film production [38].

## CHAPTER III

### EXPERIMENTAL

#### 3.1 Materials

##### 3.1.1 Model drug

Simvastatin (SV) was obtained as a gift sample from Silommedical Co., Ltd. (Thailand)

##### 3.1.2 Polymer

Chitosan, food grade,  $M_w$  500 kDa., Deacetylation 85 %, Lot No. 497613, (Seafresh, Thailand)

##### 3.1.3 Chemicals

1. Methyl acrylate: analytical grade; Sigma-Aldrich
2. 5-amino-2-mercaptobenzimidazole: analytical grade; Sigma-Aldrich
3. Basic fuchsin (pararosaniline): analytical grade; Sigma-Aldrich
4. Sodium metabisulfite: analytical grade; Sigma-Aldrich
5. Periodic acid: analytical grade; Sigma-Aldrich
6. 5, 5'-Dithio-bis(2-nitrobenzoic acid): analytical grade; Sigma-Aldrich
7. Hydrochloric acid fuming 37%: analytical grade; Merck
8. Acetic acid: AR grade; Union chemicals
9. Chloroform-D: NMR spectroscopy grade; Merck
10. Mucin from porcine stomach (type 2): analytical grade; Sigma-Aldrich
11. Potassium dihydrogen phosphate: analytical grade; Merck
12. Potassium bromide: analytical grade; Merck
13. Potassium iodide: analytical grade; Merck

14. Sodium chloride: analytical grade; Merck
15. Sodium hydrogen phosphate: analytical grade; Merck
16. Sodium hydroxide: analytical grade; Merck
17. Sodium tripolyphosphate: analytical grade; Sigma-Aldrich
18. Potassium hydroxide: analytical grade; Lab-Scan
19. Acetone, commercial grade; Merck
20. Ethanol 95 %: commercial grade; Merck
21. Methanol, commercial grade; Merck
22. Dialysis membrane with  $M_w$  cut off at 12,000 – 14,000 Da; Sigma-Aldrich

### 3.2 Instruments

Table 3.1 The Instruments used in this study

Instrument	Manufacture	Model
FTIR spectrometer	Nicolet	6700
NMR spectrometer	Varian	400 MHz
Freeze dryer	Labconco	Freeze 6
Vacuum pump	Bacthai	ME 2
Horizotal shaking water-bath	Lab-line instrument	3575-1
Micropipette	Mettler Toledo	Volumate
UV-VIS spectrometer	PerkinElmer	Lambda 80
TGA	PerkinElmer	Pyris Diamond
Scanning Electron Microscope	Philips	XL30CP
Syringe pump	Pennyful	kdScience
Small bench centrifuge	Hettich	EBA20
Particle sizer	Malvern Instruments	Zetasizer nanoseries
Ultrasonic bath	Ney Ultrasonik	28H

### 3.3 Methods

#### 3.3.1 Synthesis of Thiolated chitosan

##### 3.3.1.1 Synthesis of *N*-carboxyethyl chitosan methyl ester(MA-CS)

*N*-carboxyethyl chitosan methyl ester (MA-CS) was prepared from chitosan and methyl acrylate (MA) by Michael addition. 1 g of chitosan dissolved in 100 ml of 1% v/v acetic acid. To the solution added 0.50 ml of ME and 40.0 ml of methanol. The mixture was stirred at 60 °C for 3 days. The reaction mixture was concentrated under reduced pressure to remove excess amount of methyl acrylate and MeOH. The remaining mixture precipitated with excess acetone and harvested by centrifugation (12,000 rpm for 2 min). The pellet dialyzed (MW cut-off 12–14 kDa) against changes of 1 L of methanol for 1 days prior to being air dried to obtain MA-CS

##### 3.3.1.2 Coupling of MBI on *N*-carboxyethyl chitosan methyl ester (MBI-MA-CS)

0.1 g of 5-amino-2-mercaptobenzimidazole (MBI) dissolved in 10 ml methanol were slowly added to 100 ml of *N*-carboxyethyl chitosan methyl ester under stirring. 1-Ethyl-3-(dimethylaminopropyl)carbodiimide (EDAc) used as activate was added to the mixture. The mixture was stirred at 60°C in a nitrogen atmosphere for 2 days. The reaction mixture was precipitated with excess acetone and harvested by centrifugation (12,000 rpm for 2 min). The pellet was re-dissolved in water and dialyzed (MW cut-off 12–14 kDa) against changes of 1 L of methanol for 1 days prior to being lyophilized at -30 °C and 0.01 mbar. The dry product was stored at 4°C before use.

**Scheme 1** Synthesis flowchart of *N*-carboxyethyl chitosan methyl ester (MA-CS) and MBI-*N*-carboxyethyl chitosan methyl ester (MBI-MA-CS)

### 3.3.2 Chemical characterization

#### 3.3.2.1 Fourier transformed infrared spectroscopy (FT-IR)

The CS, MA-CS and MBI-MA-CS were prepared as potassium bromide pellets. FTIR spectra were performed by a Nicolet 6700 Fourier transform infrared (FTIR) spectrometer in the region from 4000  $\text{cm}^{-1}$  to 400  $\text{cm}^{-1}$ .

#### 3.3.2.2 $^1\text{H}$ Nuclear Magnetic Resonance spectroscopy (NMR)

$^1\text{H}$  NMR spectra were recorded on Bruker NMR spectrometer operated at 400 MHz.  $\text{D}_2\text{O}/\text{CF}_3\text{CO}_2\text{H}$  (1%, v/v) was used to dissolve 5 mg of chitosan and modified chitosan (MA-CS and MBI-MA-CS). The substitution of carboxylic and methyl ester group were determined by  $^1\text{H}$  NMR spectroscopy according to Eq. (1) as previously described [39].

$$[\text{COOMe}+\text{COOH}] (\%) = \left( \frac{[\text{H8}]}{[\text{H3-H6}]} \times \frac{5}{2} \right) \times 100 \dots\dots (1)$$

Here, [H8] is the integral of the methylene proton of MA-CS at the chemical shift 2.32 ppm and [H3-H6] is the integral of the H3, H4, H5 and H6 proton of MA-CS at the chemical shift between 3.6 and 4.2 ppm. (Figure 4.3b)

#### 3.3.2.3 Thermogravimetric analysis (TGA)

The thermal stability of each of the samples was evaluated using TGA analysis. These experiments were performed on a PerKinElmer Pyris Diamond TG/DTA machine under a nitrogen flow at a rate of 30 mL/min. Approximately 5 mg of samples were placed in the alumina pan, sealed and heated at 10 $^\circ\text{C}/\text{min}$  from 25 to 500  $^\circ\text{C}$ .

#### 3.3.2.4 Determination of the thiol group and disulfide bond content

The degrees of thiol group substitution in these modified polymers were determined spectrophotometrically using Ellman's method [30]. This reaction is now widely used for the assay of cholinesterase and the estimation of sulfhydryl groups in tissues [41]. Briefly, a 5 mg of MBI-MA-CS and control (chitosan and MA-CS) were added to 500  $\mu$ l of 0.5 M phosphate buffer pH 8.0 and then 500  $\mu$ l of Ellman's reagent (3 mg of DTNB dissolved in 10 ml of 0.5 M phosphate buffer pH 8.0) were added. The samples were incubated for 2 h at room temperature and the absorbance was measured at a wavelength of 450 nm. L-Cysteine hydrochloride standards (10–70  $\mu$ mol/l) were used to calculate the amount of thiol moieties on MBI-ME-CS.

The amount of disulfide bonds was determined that it was formed due to the oxidation by air/atmosphere during the thiolation step as described by our research group previously [42]. Briefly, 5 mg of the thiolated polymer was hydrated in 1 mL of 50 mM phosphate buffer pH 8.0 for 30 min. 600  $\mu$ L of 3% sodium-borohydride solution was added to the polymer solution, and the mixture was incubated for 2 h in an oscillating waterbath. 500  $\mu$ L of 1M HCl were added in order to destroy the remaining sodium-borohydride. After the addition of acetone (100  $\mu$ L) the mixture was agitated for 5 min. Thereafter, 1 mL of 1M phosphate buffer pH 8.5 and 200  $\mu$ L of 0.5% (w/v) DTNB dissolved in 0.5M phosphate buffer pH 8.0 were added. After incubation for 15 min at room temperature aliquots of 200  $\mu$ L were transferred to a 96-well microtitration plate and the free sulfhydryl groups were determined as described above. The amount of disulfide bonds was calculated by subtracting the quantity of free thiol groups as determined by the method described above from the total of thiol moieties present on the polymer.

### 3.3.3 *In vitro* bioadhesion of mucin to chitosan and modified chitosan

#### (a) Mucus glycoprotein assay

The Periodic Acid Schiff (PAS) colorimetric method is widely used for analysis of mucins, glycoproteins and other polysaccharides in tissues and cells [43]. The PAS colorimetric assay used for the detection of the free mucin concentration for the studies on the adsorption of mucin on CS, MA-CS and MBI-MA-CS. Two reagent were prepared. Schiff reagent contained 1% (w/v) basic fuchsin (pararosaniline) dissolved in DI water. 20 mL of 1 M HCl and 0.1g of Sodium metabisulphite was added to every 6 ml of fuchsin solution. The resulting solution was incubated at 37°C until it became pale yellow. The solution was filtered before use. Periodic acid reagent was freshly prepared by adding 10  $\mu$ L of 50% (v/v) periodic acid solution to 7 mL of 7% (v/v) acetic acid solution.

Standard calibration curves were prepared from 2 ml of mucin standard solutions (0.025-0.5 mg/mL). After adding 100  $\mu$ L of periodic acid reagent, the solutions were incubated at 37 °C for 2 h. Then, 100  $\mu$ L of Schiff reagent was added at room temperature for 30 min. 100  $\mu$ L aliquots of the solution were transferred in triplicate into a 96-well microtiter plate and the absorbance at 555 nm was recorded.

#### (b) Adsorption of mucin on chitosan and modified chitosan (MA-CS and MBI-MA-CS)

0.05% (w/v) mucin solution in three different of pH, namely the simulated gastrotinal fluid (SGF, pH 1.2 and 4.0) and the simulated intestinal fluid (SIF, pH 6.4) media, were prepared. Chitosan and its derivatives were dispersed (at 5 mg/mL final) in the mucin solutions. These were mixed, vortexed and shaken at 37 °C for 2 h. Then the dispersions were centrifuged at 12,000 rpm for 2 min. The supernatant was harvested and used for the measurement of the free mucin content. The mucin concentration was calculated by reference to the calibration curve, and the amount of

mucin adsorbed to the microspheres was calculated as the difference between the total amount of mucin added and the free mucin content in the supernatant.

### 3.3.4 Swelling study of chitosan and modified chitosan (MA-CS and MBI-MA-CS)

The swelling behaviour of CS, MA-CS and MBI-MA-CS was studied by observing the change of diameter of the film in media of different pHs at room temperature. A 1 g of each polymer was dissolved in 50 mL of 1% (v/v) aqueous acetic acid to yield a 1% (w/v) polymer solution, then the solution poured into the tray (8 ×10 cm) and air dried to obtained the CS, MA-CS and MBI-MA-CS films. The dried films were cut into 5.0 mm diameter circles and each one was immersed in one of SGF (pH 1.2), 0.1 M sodium acetate buffer (pH 4.0) and SIF (pH 6.4) media. The swelling properties were determined by measuring the change in the diameters of each film at various time intervals (0–24 h). The swelling ratio ( $S_w$ ) for each sample determined at time  $t$  was calculated from Eq. (2) as previously reported [44]

$$S_w = \frac{D_t - D_0}{D_t} \times 100 \dots \dots \dots (2)$$

where  $D_t$  is the film diameter at time  $t$  and  $D_0$  is the initial film diameter.

### 3.4 Pharmaceutical applications

In order to study a pharmaceutical application potential of modified chitosan as a drug delivery system. The microspheres were prepared by electrospray technique using simvastatin (SV) as a coronary heart drug is the representation model drug for studying the drug delivery system. The properties of drug loaded microspheres, e.g. morphology, particle size, zeta potential, encapsulation efficiency, and drug release profiles were investigated.

### 3.4.1 Preparation of drugs-loaded polymer microspheres

A 1% (w/v) chitosan and modified chitosan solution (MA-CS and MBI-MA-CS) in 1% (v/v) aqueous acetic acid was prepared. The SV drug (10, 20 and 30mg) was dissolved in EtOH and then Tween80 was added into it. The mixing of chitosan and SV solution to obtain 1:1,2:1 and 3:1% w/w of drug: polymer ratio.

Chitosan and modified chitosan microspheres were prepared by electrospray technique (Figure 3.2). A 5 ml of prepared solution placed onto the syring pump then fed the liquid through silicone tubing and into the needle. The particles generated by a high electric field applied to the solution until able to overcome the surface tension of the droplet solution. The liquid jet was collected into a coagulant bath containing 40 mL of 5% (w/v) sodium tripolyphosphate solution, stirred at 300 rpm. The microspheres were separated by centrifugation at 12,000 for 5 min and washed by DI for 3 times. Control chitosan and modified chitosan microspheres was prepared in the same method as mentioned above without SV.

The preliminary studies of electrospray parameters on the particle sizes that applied voltage was maintained at 20 kV, using a type 26 gauge needle and the working distance between the needle tip, coagulant solution is 8 cm and varying of flow rate are 1.0 ml/hr.

**Figure 3.2** Schematic diagram of the electro spray experimental equipment for preparation of SV loaded modified chitosan microspheres.

### 3.4.2 Characterization of the microspheres

#### 3.4.2.1 Scanning Electron Microscope (SEM)

The surface morphology of sample (before and after the drug loading) were examined by SEM. The samples were mounted onto an aluminum stub using double-sided carbon adhesive tape and coated with gold-palladium. Coating was achieved at 50 mA for 6 min through a sputter coater. The particles were observed via scanning electron microscope under high vacuum at an ambient temperature with a beam voltage of 10-20 kV.

#### 3.4.2.2 Particle size measurement

The particle size and size distribution of microspheres were evaluated with a particle size analyzer (Zetasizer nano series, Malvern instruments). Microspheres are suspended in an aqueous 5% (w/v) sodium tripolyphosphate solution. Size calculation was base on dynamic light scattering (DLS) method as a

software protocol. The scattered light was collected at an angle of  $90^\circ$  through fiber optics and converted to an electrical signal by an avalanche photodiode (APDS). All samples were sonicated and run in triplicate with the number of runs set to 5 and run duration set to 10 seconds.

#### 3.4.2.3 Zeta potential

Zeta potential of the microspheres were determined using particle sizer. The analysis was performed at a scattering angle of  $90^\circ$ . All samples were sonicated and run in triplicate with the number of runs set to 5 and run duration set to 10 seconds.

#### 3.4.2.4 Fourier Transform Infrared (FTIR) Spectroscopy

The FTIR spectra of the pure drug and drug loaded microspheres were examined by using the potassium bromide disk (KBr) method with a Fourier transform infrared (FTIR) spectrometry in the range of  $4000-400\text{ cm}^{-1}$ .

#### 3.4.2.3 Thermogravimetric analysis (TGA)

The thermal stability of each of the samples was evaluated using TGA analysis. These experiments were performed on a PerKinElmer Pyris Diamond TG/DTA machine under a nitrogen flow at a rate of  $30\text{ mL/min}$ . Approximately  $5\text{ mg}$  of samples were placed in the alumina pan, sealed and heated at  $10^\circ\text{C/min}$  from  $25$  to  $500^\circ\text{C}$ .

### 3.4.3 Study of the drug behavior of the microspheres

#### 3.4.3.1 Calibration curve of SV

The standard stock SV solution was prepared in 1% (v/v) EtOH. SV 5 mg was accurately weighed and dissolved with 1% (v/v) EtOH into 50 mL volumetric flask and adjusted to volume (100 ppm).

The stock SV solution was diluted to 3, 6, 9, 12, 15 and 18 ppm with 1% (v/v) EtOH in volumetric flask.

The absorbance of standard solution was determined by UV-Vis spectrophotometer at 238 nm. The 1% (v/v) EtOH was used as a reference solution. The absorbance and calibration curve of SV in 1% (v/v) EtOH was shown in appendix 1C

#### 3.4.3.2 Calibration curve of SV in pH 1.2, 4.0 and 6.4

The standard stock SV solution was prepared in 1% (v/v) EtOH in pH 1.2, 4.0 and 6.4. SV 5 mg was accurately weighed and dissolved with 1% (v/v) EtOH into 50 mL volumetric flask and adjusted by various buffers to volume (100 ppm).

The stock SV solution was diluted to 3, 6, 9, 12, 15 and 18 ppm with three different buffers in volumetric flask.

The absorbance of standard solution was determined by UV-Vis Spectrophotometer at 238 nm. The 1% (v/v) EtOH was used as a reference solution. The absorbance and calibration curve of SV in 1% (v/v) EtOH was shown in appendix 2C-4C.

#### 3.4.3.3 Determination of drug loading efficiency (%EE)

The dried SV immobilized onto modified microspheres (2 mg) were immersed in 10 mL of EtOH. The mixture was stirred at room temperature for 30

min. The supernatant of solution was collected and determined by UV-Vis spectrophotometer at 238 nm.

The actual amount of drug loaded in micrpspheres was calculated from calibration curve of SV in 1% (v/v) EtOH.

The encapsulation efficiency of SV was calculated according to the following equation. All experiments were repeated for three times.

$$\text{Drug encapsulation efficiency} = \frac{\text{Actual drug content}}{\text{Theoretical drug content}} \times 100$$

#### 3.4.3.4 *In vitro* drug release

The SV release from modified microspheres were studied in three difference buffers by dialysis bag diffusion technique. The accuarate weighted quantities of 10 mg of the spheres were enclosed in a dialysis bag with a molecular weight cut off of 3500 Da and immersed into 50 mL of the appropriate buffer in a flask. The flask was placed in a shaken water bath at speed of 100 rounds per minutes and incubated  $37 \pm 2^\circ\text{C}$ .

The 3 ml samples were withdrawn at specified time intervals ( at 0, 5, 10, 15, 30, 45 minute 1, 2, 3, 4, 5, 6 , 7, 8 and 24 hours, respectively). An equal volume of fresh dissolution medium were placed to maintain the volume constant. The released SV were analyzed by UV-Vis spectrophotometer at 238 nm.

The amount of SV released was calculated by interpolation from a calibration curves containing increasing concentrations of SV. The percentages of cumulative SV release were calculated from this equation.

$$\% \text{ Cumulative release} = \frac{\text{Amount of SV from release}}{\text{A mount of SV before release}} \times 100$$

#### **3.4.4 Statistical analysis**

All measurement were performed in experiment. Results are presented as mean $\pm$ SD. Statistical analysis was performed by one-way ANOVA using Microsoft Excel (Microsoft Corporation) with  $P < 0.05$  considered to indicate statical significance.

## CHAPTER IV

### RESULTS AND DISCUSSION

#### 4.1 Synthesis of MA-CS and MBI-MA-CS

The first step, the reaction of CS and MA to form *N*-carboxyethyl chitosan methyl ester (MA-CS) was carried out via Michael addition. The  $\beta$ -carbon in  $\alpha,\beta$ -unsaturated-carbonyl compound (MA) was attacked with the amino groups of CS (Sashiwa et al., 2003). The second step, the MBI was covalently reacted at the carboxylic group and methyl ester group of MA-CS via the formation of amide bonds (Fig. 1).

**Scheme 1** Synthesis flowchart of *N*-carboxyethyl chitosan methyl ester (MA-CS) and MBI- carboxyethyl chitosan methyl ester (MBI-MA-CS).

## 4.2 Characterization and physical properties of chitosan and modification of chitosan

### 4.2.1 Fourier-Transform Infrared Spectroscopy (FT-IR)

The FTIR spectra of CS, MA-CS and MBI-MA-CS are shown in Figure. 2. The FTIR spectrum of CS (Figure. 2a) showed a broad absorption at  $3446\text{ cm}^{-1}$  assigned to the stretching vibration of the O-H and N-H bonds. The absorption at  $2928$  and  $2900\text{ cm}^{-1}$  is related to C-H stretching. The characteristic CS peak that correspond to the amide C=O stretching and the N-H bending (amide I band) were observed at  $1645$  and  $1593\text{ cm}^{-1}$ , respectively. The absorption in the range  $1146$  to  $840\text{ cm}^{-1}$  due to the polysaccharide skeleton, including the symmetric stretching of the glycosidic bonds, C-O-C and involved skeletal vibration of the C-O stretching. After coupling of the MA onto the C2-amine groups of chitosan, the characteristic signal at  $1720\text{ cm}^{-1}$  (Figure. 2b), attributed to the stretching vibration of the C=O ester of MA-CS appeared and the peaks of N-H bending was shifted to  $1562\text{ cm}^{-1}$  (amide II band). Moreover, the broad overlapping bands and the decreasing of intensity in the  $1153$  to  $848\text{ cm}^{-1}$  range that result from the coupling of the C-N axial stretching and N-H angular deformation range. In addition, the MBI-MA-CS spectra (Figure. 2d) showed a new absorption peak at  $1640$  and  $1615\text{ cm}^{-1}$  were attributed to the amide C=O stretching and secondary amine of MBI-MA-CS, respectively. The absorption band at  $1468\text{ cm}^{-1}$  attributed to C=C stretching of aromatic. The peaks at  $612\text{ cm}^{-1}$  correspond to the thiol group that confirmed to present of thiol group on MA-CS, indicated that the successful preparation of MA-CS and MBI-MA-CS coupling.

**Figure 4.2** Representative FTIR spectra of (a) CS, (b) MA-CS, (c) MBI, (d) MBI-MA-CS

#### 4.2.2 Nuclear Magnetic Resonance ( $^1\text{H-NMR}$ )

The chemical structure of chitosan and modified chitosan (MA-CS and MBI-MA-CS) were characterized by  $^1\text{H}$  NMR are shown in Figure. 3. The peaks at chemical shifts 4.39, 3.25–3.46, 2.71 and 1.61 ppm were ascribed to the H1(GluN), H3–H6, H2 (GluN) and acetyl (GluNAc) protons in the chitosan skeleton (Figure. 3a), respectively. The appearances of new proton positions from the side chain of MA were observed at 3.1 and 2.7 ppm are assigned to the H7 and H8, respectively (Figure. 3b) that the new proton positions appeared different position when compared to the peak of MA at chemical shifts 6.3(d), 6.1(t) and 5.9(d) ppm attributed to the proton of alkene. The spectra of MBI-MA-CS showed the proton of aromatic ring at chemical shifts between 7.1 and 7.5 ppm are assigned to the H10 and H11 (Figure. 3c) that were shifted from 6.3 and 6.7. (Fig.3d). The  $^1\text{H-NMR}$  spectrums confirmed that MA-CS and MBI-MA-CS was successfully prepared.

**Figure 4.3** Representative  $^1\text{H}$  NMR spectra of (a) CS, (b) MA-CS and (c) MBI-MA-CS.

### 4.2.3 Thermogravimetric analysis (TGA)

The thermal stability and thermal behavior of chitosan and modified chitosan (MA-CS and MBI-MA-CS) were obtained by TGA. The TG and DTG curves of CS are shown in Fig. 4.4

The TG curve of CS showed two stages (Figure. 4.4a) of weight loss, the first being water loss and volatile products (6 % of the total weight) at 50 °C to 150 °C, the second stage in temperature range from 325 °C to 350 °C with the derivative thermogravimetric (DTG) peak at 326 °C and weight loss was 45% of the total weight was ascribed to the degradation of CS backbone. In contrast, the MA-CS and MBI-MA-CS showed to degrade at lower temperature than that of CS. For the first stage of MA-CS range between 50-180 °C (Figure. 4.4b) likely was due to the loss of water 10%, while the second, the thermal decomposition at 290 °C with 35 % weight loss.

The thermal decomposition of MBI-MA-CS showed two stage (Figure. 4.4c), the first from 50 °C - 170 °C being due to the evaporation of water (8% of total weight), followed by the more obvious weight loss (40 % total weight) at 308 °C that the thermal decomposition. The results was obtained from TGA curve demonstrate the loss of the thermal stability for MA-CS and MBI-MA-CS compare to CS that indicate a decrease of thermal stability by introduction of MA and MBI side chain on CS that change the crystalline structure of CS.

**Figure 4.4** Representative TGA thermograms (TG curves) of (a) CS, (b) MA-CS and (c) MBI-MA-CS.

#### 4.2.4 The substitution of MA on CS and quantification of the thiol level on MA-CS

The substitution of MA (COOH+COOMe) on CS was calculated from Eq. (1), was 14.38% (Table 4.1). Decreasing of MA was 12.64% after coupling of MBI on MA-CS.

The amount of free thiol group and disulfide bonds immobilized in the MA-CS derived polymers are summarized in Table 4.1. The MBI-MA-CS polymer derived from a 1:0.1 (w/w) ratio of MBI-MA-CS exhibited of free thiol groups of 11.86  $\mu\text{mol/g}$  and the level of total disulfide groups about 6.54  $\mu\text{mol/g}$  (Appendix A).

**Table 4.1** Substitution of MA on MA-CS and the level of free thiol and disulfide groups

Batch	The substitution of MA (%) [COOH+COOMe ]	Total thiol Groups ( $\mu\text{mol/g}$ ) ( $\pm\text{SD}$ , n=3)	Total disulfide Groups ( $\mu\text{mol/g}$ ) ( $\pm\text{SD}$ , n=3)
CS	-	-	-
MA-CS	14.38	-	-
MBI-MA-CS	12.64	11.86 $\pm$ 0.01	6.54 $\pm$ 0.02

### 4.3 Mucoadhesive properties

#### 4.3.1 Assessment of the mucoadhesive behavior of CS and the modified CS (MA-CS and MBI-MA-CS) by mucus glycoprotein assay

The mechanism of mucoadhesion has been theoretically reported to be based on the six general components of electrostatic, wetting, adsorption, diffusion,

mechanical and fracture theories [30, 35]. Many methods have been employed to evaluate these interactions *in vitro* and *in vivo*.

In this study, porcine mucin type II was selected which is typically used in mucoadhesion assays due to its lower batch-to-batch variability and higher between assay reproducibility [11]. As a strong interaction exists between mucin and CS or its derivatives, mucin should be spontaneously adsorbed onto the surface of the CS or its derivatives.

Periodic acid: Schiff (PAS) colorimetric method was used to qualify mucin-conjugated polymer bioadhesed strength [42, 45] in the simulated gastrointestinal fluid in pH 1.2 (SGF), pH 4.0 and pH 6.4 (SIF) that a strong interaction exists between mucin and CS, modified CS (MA-CS, MBI-MA-CS). The mucin should be spontaneously adsorbed on the surface of the CS and modified CS. The mucoadhesive property of the chitosan and its derivatives was assessed by suspension of mucin in their aqueous solutions (in pH 1.2, 4.0 and 6.4) at room temperature. The linearity range for mucin at the wavelength of detection at 555 nm was obtained as 0.1-0.5 mg/mL. The linear equations obtained by least square method were  $y = 0.257x - 0.021$ ,  $y = 0.758x + 0.020$  and  $y = 1.266x + 0.009$  in pH 1.2, 4.0 and 6.4, respectively (Appendix B).

#### **4.3.2 Adsorption of mucin on polymer**

The amount of mucin that was adsorbed onto the polymer depend on ionization of sialic acid of the mucus glycoprotein and polymer that is to say the value of  $pK_a$  and  $pI$  for sialic acid and mucin are 2.6 and ~3-5, respectively [32]. Therefore the different forms of the glycoprotein will be influenced by the pH value of the environment.

**Table 4.2:** Comparison of chitosan and modified chitosan to mucoadhesive property

<b>Batch</b>	<b>Absorbed of mucin at pH 1.2 (mg) (±SD, n=3)</b>	<b>Absorbed of mucin at pH 4.0 (mg) (±SD, n=3)</b>	<b>Absorbed of mucin at pH 6.4 (mg) (±SD, n=3)</b>
CS	0.07±0.01	0.33±0.01	0.33±0.01
MA-CS	0.72±0.01	0.93±0.01	0.40±0.01
MBI- MA-CS	0.77±0.01	0.97±0.02	0.66±0.02

At pH = 1.2, the resulting of the increment of mucoadhesiveness from CS to MA-CS about 10.28 times which is greater than that from CS to MBI-MA-CS with about 11 times (Table 4.2 and see Figure.4.5). The amino groups of CS backbone were protonated to  $\text{NH}_3^+$  groups (pKa value of CS are 6.5-6.8) while the less ionization of sialic acid (COOH and  $\text{SO}_3\text{H}$  groups) on the mucin leading to reduce the potential interaction with CS. When the CS was coupled with MA, the aliphatic side chain of MA can further participate hydrophobic interaction with  $\text{CH}_2/\text{CH}_3$  of mucin side chain (Figure. 4.6). Moreover, the hydroxyl end group of side chain can form hydrogen bonding with  $-\text{COOH}$ ,  $\text{SO}_3\text{H}$  of mucus glycoprotein leading to increase the mucoadhesiveness. For the MBI-MA-CS containing  $-\text{SH}$  group, it exhibited to stronger mucoadhesiveness than that of CS but showed non-significant increase in the mucin absorption level when compare to MA-CS. This is probably due to the steric effect of aromatic ring that hinder the interaction between the hydrogen bonding of  $-\text{COOH}/-\text{COOCH}_3$  of MA and  $-\text{COOH}/\text{SO}_3\text{H}$  of mucin. Furthermore,  $-\text{SH}$  groups on MBI-MA-CS can react with  $-\text{SH}/\text{S-S}$  (cysteine and cystine) on mucin that formed disulfide via only oxidation reaction. The tendency of the increment of mucoadhesiveness is similar in that for pH 4.0. At this pH, the partial amino groups of CS were protonated ( $\text{NH}_3^+$ ), the ionization of sialic acid

(COO<sup>-</sup> and SO<sub>3</sub><sup>-</sup> groups) increased leading to the ionic interaction with CS. The results are also consistent with pH 1.2 that the mucoadhesiveness increased from CS to MA-CS about 2.81 times and from CS to MBI-MA-CS greater than about 2.94 times. Therefore, the effect of electrostatic, hydrogen and hydrophobic effects impact on the mucoadhesion of CS, MA-CS and MBI-MA-CS in lower pH range.

At pH 6.4, the amino groups of CS was deprotonated therefore, electrostatic interaction between between the positive charges of the CS backbone (NH<sub>3</sub><sup>+</sup>) with either COO<sup>-</sup> or SO<sub>3</sub><sup>-</sup> groups on the mucin decreased. Consideration the mucoadhesiveness of MA-CS, the resulting of the increment of mucoadhesiveness from CS to MA-CS about 1.25 times because of the hydrophobic effect, the -CH<sub>3</sub> moieties and -CH<sub>2</sub> side chain on polymer interact in part with the -CH<sub>3</sub> groups on the mucin side chains. Furthermore, MBI-MA-CS found that a significant increase the mucin absorption level that from CS to MBI-MA-CS about 2.06 times. The reactive form of thiolate anions, -S<sup>-</sup> (pKa ~2.6), this may have lead to a greater extent of the both of oxidation and nucleophilic attack. This can be explained by the formation of covalent disulfide bonds between the thiol group (-SH) on polymer and cysteine-rich (-SH) subdomains of the mucus glycoprotein (Figure. 4.6) [14]. The higher the amount of mucin was bound onto the polymer. Therefore, the effect of hydrogen, hydrophobic and covalent effects impact on the mucoadhesion of CS, MA-CS and MBI-MA-CS in higher pH range.

**Figure.4.5** Adsorption of mucin on CS and modified CS at pH 1.2, 4.0 and 6.4.

Data are shown as the mean $\pm$  SD and are derived from three independent repeats.

**Figure.4.6** Representative mucoadhesive mechanism of the CS and modified CS

#### 4.4 Swelling study

The swelling properties are of paramount importance to consider as it influences the adhesive cohesive properties as well the drug release. However, Most mucoadhesive delivery system are addressed to the small intestine where they reach the mucosal membrane in partially hydrated form. Excessive water uptake results in overhydration, loss of cohesive properties and leads to unsuccessful mucoadhesiveness. Therefore, a moderate swelling behavior is indispensable for adequate interdiffusion between polymers chains and mucosa representing the basis for sufficient adhesive [46].

The swelling can be affected by many factors, such as the cross-linking density and the hydrability of the materials, and the ionic strength and pH value of the media [47]. In general, the swelling behavior was measured in three broadly isotonic buffer solutions (the gastrointestinal tract), being SGF (pH 1.2), 0.1 M acetate buffer (pH 4.0) and SIF (pH 6.4) and the swelling ratio was calculated using Eq. (2) as detailed in Section 3.3.5.

The results, as the variation in the swelling ratio with time. The CS, MA-CS and MBI-MA-CS polymers that showed essentially the same pattern (data not shown) are shown in Figure 4.7. As the pH value increased the degree of observed swelling decreased. In addition to, the MA-Chitosan and MBI-MA-Chitosan presenting a lower swelling ratio than that of chitosan in all three different pH media. This may be attributed to the fact that the attachment of MA and MBI on chitosan reduced the overall hydrophilicity, lead to a diminished water uptake compare to chitosan. The reduce swelling behavior as a consequence of the pronounced hydrophobic character of MA-chitosan and MBI-MA-chitosan. Moreover, this could be explained from the pH-dependent charge balance of MBI-MA-Chitosan, MA-Chitosan and chitosan, and so the degree of interaction between these three polymers is modified in accord with their charge balance that showed the mechanism of swelling in Figure 4.8.

**Figure 4.7** Swelling behavior of the CS, MA-CS and the thiolated CS derivatives (MBI-MA-CS). Data are shown at equilibrium (24 hr swelling time) as the mean $\pm$ 1 SD and are derived from three independent repeats.

In strongly acidic medium (pH 1.2), the high swelling behavior can be explained by amino group of chitosan protonated ( $\text{NH}_3^+$ ) and hydrogen bonds were dissociated, inducing the network to become loose and leading to an increase degree of swelling. This cause repulsions in the polymer chains allowing more uptake of water to the polymer. At pH 4.0, the partial amino group of chitosan were protonated ( $\text{NH}_3^+$ ), repulsion in the polymer chains reduced leading to decrease degree of swelling. For MA-Chitosan and MBI-MA-Chitosan polymers that showed essentially the same pattern in the both pH 1.2 and 4.0 are shown in figure 4.7. There is an overall decrease in swelling ratio due to MA-CS was contained of ester groups and carboxylic groups of MA side chain about 14% caused hydrogen bonding between polymer chain resulting that decreased its water absorption. In order to investigate of MBI on MA-Chitosan was more uptake water than MA-Chitosan at pH 4.0 due to, the thiolate groups become charged anionic, S<sup>-</sup>, which represents the reative oxidation form and thereby lead to electrostatic replusion between the polymer segments. Moreover, the investigate of aromatic thiolated leading to increased steric effect that prevented the intramolecular interations of the CS-NH<sub>2</sub> that increased of swelling when compare to MA-CS.

At a high pH (pH 6.4), amino groups of CS become to the almost complete deprotonation, repulsion in the polymer chains reduced allowing shrinking. Furthermore leading to a re-association of the interchain hydrogen bonds and consequently to weaker interactions between the polymer chains and the aqueous media, inducing to decrease its water absorption. For MBI-MA-CS was more uptake water than MA-CS (Figure 4.7) due to the thiolate groups remain charged anionic, S<sup>-</sup>, which lead to electrostatic repulsion between the polymer segments (Figure 4.8) that increased of swelling when compare to MA-CS but swelling decreased when compare to CS because the investigate of aromatic thiolated of MBI-MA-CS caused steric effect that prevented the intramolecular interactions of the CS-NH<sub>2</sub>. However, the polymers have only a relatively low density of thiol groups compared to that for the amine groups, and so the affects of the amino group are dominant.

**Figure 4.8** Representative swelling mechanism of the MBI-MA-CS in pH 1.2, 4.0 and 6.4

#### 4.5 Morphology

The CS, MA-CS and MBI-MA-CS used in pharmaceutical dosage forms, particularly as a vehicle for controlled drug delivery.

The particles generated by applying a high electric field to the polymer solution until it able to overcome the surface tension of the stream to give continuous stream (drop) and drops into collected beaker containing 5% tripolyphosphate (TPP) as coagulant used to prepare of microparticles by the electrostatic interaction between chitosan and the tripolyphosphate (TPP) polyanion [48].

The microparticle obtained by electrospraying can be controlled by adjusting the operation parameters. In this work, the high voltage power supply was used at about 21 kV that electrostatic repulsions at the liquid level on the Taylor cone so that the droplets became smaller [49].

Next, With this applied voltage, the working distance was increased to higher than 8 cm, leading to increase the travel time from the tip of the needle to the coagulant, therefore, the strength of electrical charge at the droplets will be lost, consequently, increasing in the particle size. Whereas, when decreased the distance lower than 8 cm, the strength of the electric field is increased, but the particle size is larger, because a small distance can impair full solvent evaporation and consequently, wet microspheres impact the collector, leading to collapsing, coalescence and broad size distributions [50]. Therefore, in this work, the distance was selected at 8 cm.

The flow rate, the injection with decreased flow rate leading to reduce the size due to i) The collecting of charge increased on solution and then applied voltage resulting that electrostatic repulsions until the droplets became smaller ii) the evaporation of solvent completed, which is not possible with high flow rates. The effect of gauge has little effect on morphology or size of particles. A smaller gauge (26 G) can produce a narrower size distribution [51].

Therefore, The preliminary studies of electrospray parameters as follows: high voltage power supply at 21 kV, working distance of 8 cm, flow rate, 0.5 ml/h and needle gauge 26 G. The results from studies of CS, MA-CS and MBI-MA-CS microparticles fabrication by the electrospraying technique showed that the successfully prepared.

#### 4.5.1. CS and modified CS (MA-CS and MBI-MA-CS)

The SEM micrographs of CS, MA-CS and MBI-MA-CS microspheres were shown in Figure 4.9.

**Figure 4.9** Representative SEM images of CS (1a-b), MA-CS (2a-b) and MBI-MA-CS (3a-b) without SV.

The surface morphological appearance of CS microspheres was compared with the modified CS (MA-CS and MBI-MA-CS) microspheres that without simvastatin, both of the CS and modified CS microsphere were in a generic spherical shape. Smoothness on the surface could be clearly seen at high magnification and without visible pores. This may be attributed to the fact that modified chitosan successfully fabricated to spherical shapes.

#### 4.5.2. CS and modified CS (MA-CS and MBI-MA-CS) with SV encapsulation

Figure 4.10 showed the morphology of the SV-loaded CS, MA-CS and MBI-MA-CS particles were of an acceptable spherical shape, although slightly flattened, and were smooth surfaced without visible pores.

(3a)

(3b)

(4a)

**Figure 4.10** Representative SEM images of CS (a), MA-CS (2a-b), MBI-MA-CS (3a-b) with 1%SV and MBI-MA-CS (4a) with 4%SV.

#### 4.5.3 Particle size, size distribution

Size distribution and particle size of microspheres (CS, MA-CS and MBI-MA-CS) with and without SV loading were presented in Table 4.3

The size of dried particles measured by SEM showed that CS, MA-CS and MBI-MA-CS without SV were approximately 4.5, 2.0 and 1.7  $\mu\text{m}$ , respectively. After 1%SV loaded into CS, MA-CS and MBI-MA-CS, the particle sizes are larger were approximately 5.4, 2.8 and 2.6  $\mu\text{m}$ , respectively. While, the particle size of MBI-MA-CS with 4%SV loading was of 3.3  $\mu\text{m}$  was larger than that of with 1% loaded SV and without SV, indicating that the particles could encap more drug.

When considering the size particles and size distribution of the swollen particles measured by particle size analyzer found that CS and modified CS (MA-CS and MBI-MA-CS) without SV particles size was approximately 4.65, 2.3 and 1.98  $\mu\text{m}$ , respectively with PDI approximately 0.73, 0.45 and 0.39, respectively. PDI was used to measure for the width of the particle size distribution (from 0 = monodisperse to 1 = polydisperse).

In case of the size distributions of CS and modified CS (MA-CS and MBI-MA-CS) with SV microspheres showed that they were in the range approximately from 3.53-5.62  $\mu\text{m}$  with PDI from about 0.49 to 0.75. In addition, when SV was loaded onto polymer it results in increasing the mean particle size and size distribution of spheres. Furthermore, The dried and swollen particle sizes were not significantly different, the result of the swollen particle (before and after SV loading) corresponding to particle size was measured by SEM.

#### 4.5.4 Zeta potential ( $Z_p$ )

Zeta potential measurements will give information about the overall surface charge of the particles and how this is affected by changes in the environment (e.g. pH, presence of counter-ions, adsorption) [51]. When considering the zeta potential, that is surface charge, it can greatly influence particle stability in suspension through the electrostatic repulsion between particles.

The surface of CS microparticles was found to possess negative charge of -15.12 mV and -18.38 for MA-CS because of effect of TPP. The surface negative charge of MBI-MA-CS were increased -21.45 mV (Table 4.3) due to S- anion on surface and effect of TPP.

Zeta potential values are also of interest for the characterization of the microspheres since SV-loaded microspheress display  $Z_p$  values -13.30, -14.51 and -18.15 mV (1%SV-CS, 1%SV-MA-CS and 1%SV-MBI-MA-CS, respectively) as seen in Table 4.3. Zeta potential data suggest the potential physical stability of microspheres in aqueous dispersion state and confirm the presence of SV on microspheres surface.

**Table 4.3** Effect of compositions on morphology of the microspheres

Abbreviations	Shape	Particle size <sup>1</sup> ± SD (µm)	Particle size <sup>2</sup> ± SD (µm)	Zetapotential (mV)	Polydispersity Index (PDI)
<b>Without SV</b>					
CS	Spherical	4.5±0.05	4.65±0.09	-15.12±1.20	0.73±0.10
MA-CS	Spherical	2.0±0.15	2.30±0.15	-18.38±0.87	0.45±0.15
MBI-MA-CS	Spherical	1.7±0.08	1.94±0.13	-21.45±0.68	0.39±0.01
<b>With SV</b>					
1%SV-CS	Spherical	5.4±0.05	5.62±0.08	-13.30±1.33	0.75±0.05
1% SV-MA-CS	Spherical	2.8±0.15	3.12±0.15	-14.51±0.10	0.53±0.05
1% SV-MBI-MA-CS	Spherical	2.6±0.12	2.81±0.20	-18.15±1.43	0.49±0.15
4%SV-MBI-MA-CS	Spherical	3.3±0.05	3.53±0.05	-16.08±0.97	0.67±0.02

<sup>1</sup>Particle size measured by SEM

<sup>2</sup>Particle size measured by particle size analyzer

**Figure 4.11** Schematic microstructure of SV-loaded CS, MA-CS and MBI-MA-CS microsphere

The microstructure of SV-CSSV-MA-CS and SV-MBI-MA-CS microspheres were speculated as Figure 4.11 to explained the encapsulated SV of polymers. It could be understood by associating the polymer solidification process with the SV loading process. With the solidification process proceeded, the SV was hindered because the structure of microspheres became compact due to the matrix formation between TPP and CS.

### Mucoadhesiveness of microspheres

Mucoadhesiveness of microspheres was measured as a way to test their ability to bind to the mucosal surface of the body (mucoadhesiveness). The results of *in vitro* mucoadhesive of the spheres with mucin in three different buffers (pH 1.2, 4.0, and 6.4) are shown in Table 4.4 by PAS method.

**Table 4.4** Mucoadhesive property of the CS and modified CS microspheres with SV

Abbreviation	Adsorbed of mucin at pH 1.2 (mg) ( $\pm$ SD, $n=3$ )	Adsorbed of mucin at pH 4.0 (mg) ( $\pm$ SD, $n=3$ )	Adsorbed of mucin at pH 6.4 (mg) ( $\pm$ SD, $n=3$ )
SV-CS	0.06 $\pm$ 0.01	0.29 $\pm$ 0.01	0.27 $\pm$ 0.01
SV-MA-CS	0.42 $\pm$ 0.01	0.68 $\pm$ 0.01	0.29 $\pm$ 0.02
SV-MBI-MA-CS	0.44 $\pm$ 0.01	0.73 $\pm$ 0.01	0.35 $\pm$ 0.02

At the low pH (SGF, pH 1.2), the mucoadhesive of the MA-CS and MBI-MA-CS with SV loading exhibited excellent mucoadhesiveness with 7- and 7.33-fold higher than that of the native chitosan. Moreover the MA-CS and MBI-MA-CS loaded SV stronger mucoadhesive property compared to that of the unmodified CS at pH 4.0 and 6.4. At pH 4.0, the SV-MA-CS and SV-MBI-MA-CS microspheres showed mucoadhesiveness about 2.34- and 2.51- fold. For at the pH 6.4, the SV-MA-CS and SV-MBI-MA-CS microspheres showed approximately 1.07- and 1.29-fold, respectively. When considering the mucoadhesiveness of CS and modified CS microspheres displayed a fold strongmucoadhesive property. From these results indicated that the electrostatic effects, indicating that after the CS and modified CS formed polyelectrolyte complex with TPP, the carboxylate groups of TPP were interacted with protonated amino groups of chitosan through electrostatic interaction, which is likely to be due to the fact that the influence of the positive charge of CS was not enough to increase the mucoadhesion.

## 4.6 Characterization of microsphere

### 4.6.1 Fourier transform infrared spectroscopy (FTIR)

FTIR spectroscopy was used to determine the chemical interaction between the drug and the CS and modified CS in the microspheres, samples of 1%SV-CS, 1%SV-MA-CS and 1%SV-MBI-MA-CS were investigated and displayed in Figure 4.12.

The FTIR spectrum of SV (Figure. 4.12a) as can be seen, the -OH stretching absorption band at  $3547\text{ cm}^{-1}$ . The absorption band at  $3012$ ,  $2952$ , and  $2872\text{ cm}^{-1}$  were attributed to the C-H stretching vibrations. The main characteristic peaks of SV at  $1721$  and  $1695\text{ cm}^{-1}$  were due to the stretching bands of ester and lactone carbonyl group. The C-H in-plane bending vibration and skeletal C-C vibrations are observed in the region  $1350\text{-}950\text{ cm}^{-1}$ . The C-H out-of plane bending modes are usually of weak intensity arises in the region  $600\text{-}900\text{ cm}^{-1}$ [50].

The FTIR spectrum of 1%SV-CS microspheres are shown in Figure. 4.12b, there were additional absorption peaks at  $1711\text{ cm}^{-1}$  corresponding to the ester stretching peaks of SV. The peak at  $1225\text{ cm}^{-1}$  was due to the C-H in-plane bending vibration. The peak at  $894$ ,  $795$  and  $664\text{ cm}^{-1}$  correspond to C-H in-plane bending vibrations of SV. These SV characteristic peaks were shifted in the formulations suggesting definite interactions between SV and CS.

For the 1%SV-MA-CS microspheres (Figure. 4.12c), also showed the peak at  $1715\text{ cm}^{-1}$  as C=O ester stretching. There were additional absorption peaks at  $2960\text{ cm}^{-1}$  and  $2963\text{ cm}^{-1}$  were due to C-H stretching vibrations of SV.

The FTIR spectra of 1%SV-MBI-MA-CS microspheres are shown in Figure 4.12d. As can be seen, the characteristic peak at  $2923\text{ cm}^{-1}$  and  $1709\text{ cm}^{-1}$  corresponding to the C-H stretching vibrations and ester stretching peaks of SV, respectively. The other peaks of 1%SV-MBI-MA-CS and 1%SV-MA-CS have nearly additional absorption in the position of SV and 1%SV-CS.

When considering SV loaded on CS and modified CS, it was observed that the IR spectra of them have the nearly in the position of the characteristic peak of SV but maybe shifted wave number from pure SV because of effect TPP, The FTIR

spectrum appeared can be confirming the successful loading of SV on CS and modified CS (MBI-MA-CS)microparticle.

**Figure 4.12** FTIR spectra of (a) SV, (b) 1%SV-CS, (c) 1%SV-MA-CS and (d) 1%SV-MBI-MA-CS microspheres.

#### 4.6.2 Thermogravimetric analysis (TGA)

Thermogravimetric analysis (TGA) is a useful technology to characterize the thermal behavior of materials, which is correlated to their structure, and can further the presence of interaction between chitosan and SV. The TGA thermograms of the CS and modified CS (MA-CS and MBI-MA-CS) microparticles with SV loading were shown in Figure 4.13.

The TGA thermograms for SV loaded CS (Figure. 4.13b) showed the second stages of weight loss. The first decomposition peak, due to water evaporation, was followed by a two-stage, chitosan decomposition occurred in temperature range from 325 °C to 350 °C with the derivative thermogravimetric (DTG) peak at 329 °C (20% of total weight). Furthermore, the DTG peak of SV-CS increased when compared with pure CS. This might be attributed to SV was entrapped by CS.

The thermal decomposition for the SV loaded MA-CS are shown in Figure. 4.13c. The first from 50 °C - 150 °C being due to the evaporation of water (5% of total weight). Afterwards, the degradation of MA-CS showed the thermal decomposition at 309 °C with 25% weight loss. For the TGA curve of SV loaded MBI-MA-CS show the combination of MBI-MA-CS and SV in second stages (Figure. 4.13d). The thermogram was shown a first from 50-150 °C due to the loss of water. The second stage showed the thermal decomposition (DTG) at 315 °C corresponding to the degradation of MBI-MA-CS with 35% weight loss. A suggest that the shift of the last decomposition temperature of the SV-MBI-MA-CS to a higher value, compared to that seen with MBI-MA-CS, which the result of inter- and intra-molecular disulfide interactions.

The results were obtained from TGA curve of SV loaded CS, MA-CS and MBI-MA-CS showed a higher polymer thermal stability. It is well established that intramolecular interactions increase the thermal stability of polymers, and so leads to a higher decomposition temperature.

**Figure 4.13** TGA thermogram of (a) SV, (b) 1% SV-CS, (c) 1% SV-MA-CS microspheres and (d) 1% SV-MBI-MA-CS microspheres

#### 4.7. Evaluation of drug encapsulation efficiency (%EE)

The percentages of encapsulation efficiency (%EE) of the SV loaded CS, MA-CS and MBI-MA-CS microspheres were given in Table 4.3 that were analyzed using UV/Vis spectroscopy at  $\lambda_{\max} = 238$  nm, with the linear regression equations obtained by the least square method being  $y = 0.055x - 0.017$ , for the assay in ethanol (Appendix 1C).

In this work, the amount of SV, which is loading on encapsulation efficiency was investigated to achieve the high percentage of encapsulation efficiency. The 1%SV loaded CS, MA-CS and MBI-MA-CS were 53.0%, 70.9% and 64.83% encapsulation efficiency, respectively. The drug entrapment increased for modified CS. This result showed that the compatibility between SV and modified CS were increased. Moreover the increasing of SV loaded MBI-MA-CS from 1% to 2% and 4% found that the increased encapsulation efficiency were 70.45% and 82.10%, respectively. (Table 4.5)

This result explained that the electrospray technique can produce high percentage encapsulation at about 80%.

**Table 4.5** Encapsulation of SV loaded polymer microspheres\*

Formulations	% Encapsulation
1%SV-CS	53.0±0.03
1%SV-MA-CS	70.90±0.01
1%SV-MBI-MA-CS	64.83±0.01
2%SV-MBI-MA-CS	70.25±0.02
4% SV-MBI-MA-CS	82.10±0.01

\* mean ± SD ( $n=3$ )

#### 4.8. *In vitro* SV release profiles

The release of SV drug from CS and modified CS microspheres were performed at a function of time intervals in buffers pH 1.2, 4.0, and 6.4 (SGF, vaginal fluids, and SIF, respectively) at  $37\pm 1^\circ\text{C}$ . The linear equations of SV calibration curve obtained by the least square method being  $y = 0.053x - 0.029$ ,  $y = 0.045x - 0.016$  and  $y = 0.057x - 0.022$ , for the assay in pH 1.2, 4.0 and 6.4, respectively (Appendix 2C-4C) (Figure 4.14-4.17).

**Figure 4.14** Release profiles of 1% simvastatin (from CS, MA-CS and MBI-MA-CS in pH 1.2, 37°C (average  $\pm$  SD,  $n=3$ ).

Figure 4.14-4.16 showed the releasing profiles of SV in three different buffers (pH 1.2, 4.0, and 6.4) from CS and modified CS particles.

The release profiles of the 1%SV loaded CS and modified CS shows the initial burst release in the early stage. The burst release (1 h) was due to the presence of more free drug on the particle surface. The cumulative drug release percentage are approximately 86%, 75% and 83% within hours for CS, MA-CS and MBI-MA-CS in pH 1.2 respectively. The tendency of the cumulative drug release profiles is similar in those for pH 4.0. At the pH 4.0 (Figure 4.15), the cumulative drug release percentages of CS, MA-CS and MBI-MA-CS were about 82%, 62% and 73%,

respectively. Moreover, the release behavior in pH 6.4 (Figure 4.16) was significantly lower than that in pH 1.2 and 4.0. Most of SV released from the spheres in the first 12 h.

Considering the cumulative drug release percentages of MBI-MA-CS were more than those from of MA-CS in all pH medium, indicating that MBI-MA-CS is suitable for sustained release of SV than pure SV and SV loading SV.

The results were due to effect of the swelling of polymer. When considering the cumulative drug release, the MA-CS and MBI-MA-CS microspheres could prolong release of SV for the all three tested pH within the first 4 hr up to about 40% and SV was still sustained release within 12 h due to the low swelling behavior of polymer in pH 1.2, 4.0 and 6.4 for the both MA-CS and MBI-MA-CS.

**Figure 4.15** Release profiles of simvastatin (1% SV from CS, MA-CS and MBI-MA-CS) in pH 4.0, 37°C (average  $\pm$  SD,  $n=3$ )

**Figure 4.16** Release profiles of simvastatin (1% SV from CS, MA-CS and MBI-MA-CS in pH 6.4, 37°C (average $\pm$  SD,  $n=3$ ).

As a function of pH, presents the releasing profiles of SV from MBI-MA-CS in three different buffers (pH 1.2, 4.0, and 6.4) were shown on Figure 4.17.

**Figure 4.17** Release profiles of simvastatin (SV) from MBI-MA-CS in three different buffers, 37°C (average  $\pm$  SD,  $n=3$ )

Regarding the formulation containing thiol group (MBI-MA-chitosan), the results indicated that, after 6 h, 63% of SV (Fig. 4.17) was released from polymer matrices. The presence of thiol moieties led to the formation disulfide bonds within the matrix microspheres. This cross-linking process might provide a tightened three-dimensional polymeric network leading to a more controlled drug release and improved the swelling behavior which is advantage for the diffusion of drug molecules. Additionally, their drug release is responsible for the swelling ratio of the microsphere with changing pH of the medium (4.0 and 6.4) found that the cumulative SV release shows results in pH 1.2 > pH 4.0 > pH 6.4 (Fig. 7b). This results indicated that the higher swelling ratios of the polymer create larger surface areas to diffuse the drug.

The *in vitro* release profiles of 1% and 4% SV load MBI-MA-CS microspheres were investigated in pH 1.2 for 12 h (Figure 4.18).

**Figure 4.18** Release profiles of 1% and 4% simvastatin (SV) from MBI-MA-CS in pH 1.2 buffers, 37°C (average  $\pm$  SD,  $n=3$ )

The cumulative release of SV showed that the microspheres can be prolonged release of SV within the 12 h. The release profiles of the 4%SV load MBI-MA-CS show the initial burst release in first stage (1 h) with higher than that of 1%SV-MBI-MA-CS. The burst release was considered to be due to the presence of more free drugs on the particle surface and larger diffusion area of the microspheres. Moreover, about 50% of SV was released in 4h and 1 h for 1%SV-MBI-MA-CS and 4%SV-MBI-MA-CS formulation, respectively, and still sustained released within 12 h.

The tendency of cumulative release from 1% and 4% SV-MBI-MA-CS at pH 4.0 and 6.4 is similar pH 1.2 (Figure 4.19-4.20).

Overall, from these results indicated that SV loaded modified CS formulation released the drug slowly than CS.

**Figure 4.19** Release profiles of 1% and 4% simvastatin (SV) from MBI-MA-CS in pH 4.0 buffers, 37°C (average $\pm$  SD,  $n=3$ )

**Figure 4.20** Release profiles of 1% and 4% simvastatin (SV) from MBI-MA-CS in pH 6.4 buffers, 37°C (average $\pm$  SD,  $n=3$ )

## CHAPTER V

### CONCLUSION AND SUGGESTION

#### 5.1 Conclusion

In this work, the thiolated CS was synthesized by coupled MA on CS via the Michael addition and then thiolation of MBI was covalently reacted at the carboxylic group and methyl ester group of MA-CS using EDC as activator. The substitution of MA was calculated about 14.38% by  $^1\text{H}$  NMR. The amount of thiol groups (MBI) immobilized on MA-CS and disulfide bond were displayed 11.86 and 6.54  $\mu\text{mol}$  thiol groups per gram of polymer, resulted in strongly improved mucoadhesive properties.

The mucoadhesiveness was determined by Periodic acid: schiff (PAS) colorimetric method was used to qualify mucin-conjugated polymer bioadhesed strength in the simulated gastrointestinal fluid (pH 1.2, 4.0 and 6.4) MA-CS and MBI-MA-CS increased 10.28 and 11-fold at pH 1.2, while at pH 4.0 increased  $\sim 2.81$  and 2.94-fold, at pH 6.4 increased only  $\sim 1.25$  and 2.06-fold. The data suggests that the lowest pH (1.2) shows the highest mucoadhesive property.

Because of these characteristics, the obtained thiolated CS (MBI-MA-CS) appear to be promising novel polymers for the development of various drug delivery carriers at mucus sites. The electrospray ionization was used to prepare CS and modified CS microspheres for simvastatin (SV) controlled release.

Microspheres of CS and modified CS can be obtained by fixing, the parameters as follows: working distance of 8 cm, needle gauge of 26 G, flow rate of 0.5 mL/h, stirring rate of 400 rpm and high voltage of 20 kV. The morphology of microspheres was obtained by SEM, showed a good spherical shape that well form. The swollen particle sizes of microspheres were 1-5  $\mu\text{m}$  in the range measured by particle size analyzer. The encapsulation of 1%SV loaded CS, MA-CS and MBI-MA-CS

microspheres showed 53, 70 and 64%, respectively. The drug entrapment increased for modified CS. This result showed that the compatibility between SV and modified CS were increased. Moreover, increasing of SV loaded MBI-MA-CS from 1% to 4%SV-polymer (w/w) microspheres found that increased from 64 to 82% drug entrapment. The SV-polymer microspheres can be prolonged release of SV. It was found that the release profiles of simvastatin were greatly improved upon using modified chitosan within 12 hours due to lower swelling of modified CS leading to a more controlled and sustained drug release. Mucoadhesiveness of MA-CS and MBI-MA-CS microspheres with SV were displayed 7- and 7.33-fold at pH 1.2, respectively. Hence, the advantages of the controlled release system based on the mucoadhesive polymer can be improved by using the MA-CS and thiolated chitosan.

## 5.2 Suggestion

The problem of SV was the poorly absorbed from the gastrointestinal (GI) tract with less than 5%.

We are interested in studying the oral bioavailability of SV and investigating its intestinal absorption. The *in situ* intestinal absorption of SV encapsulated in CS and modified CS will be performed in animal model. The intestinal absorption mechanism should be investigated. The pharmacokinetics will be performed to evaluate the potential of microparticles in the further step as an oral delivery carrier for SV.

**Table 3A** Absorbance disulfide groups of MBI-MA-CS by UV spectrometer.

Batch	Abs.	Abs.	Abs.	Total thiol (μM)	disulfide (μM)	disulfide (μmol/g)
MBI-MA-CS	0.987	0.990	1.08	124.7	32.25	6.54

## **APPENDIX B**

### **Calibration curve of mucin (type II)**

The concentration versus peak absorbance mucin glycoprotein (type II) determined by UV as the same condition described in chapter III is presented in Table 1B. The plot of calibration curve of mucin is illustrated in Figure 1B

**Table 1B** Absorbance of various concentrations of mucin (type II) at pH 1.2, 4.0, and 6.4 UV spectrophotometer

Concentration (mg/2mL)	Absorbance		
	HCl (pH 1.2)	Acetate buffer (pH 4.0)	PBS (pH 6.4)
0.2	0.063	0.159	0.260
0.4	0.131	0.324	0.527
0.6	0.184	0.498	0.766
0.8	0.224	0.635	1.000
1.0	0.275	0.762	1.290

**Figure 1B** Standard curve of mucin at pH 1.2, 4.0, and 6.4

**Table 2B** Absorbance of free and adsorbed mucin CS, MA-CS and MBI-MA-CS in pH 1.2 by UV spectrophotometer.

Batch	Abs.	Abs.	Abs.	Free mucin (mg)	Absorbed mucin (mg)	SD
CS	0.320	0.325	0.336	0.930	0.070	0.011
MA-CS	0.089	0.088	0.100	0.278	0.722	0.009
MBI-MA-CS	0.085	0.078	0.081	0.235	0.765	0.009

**Table 3B** Absorbance of free and adsorbed mucin CS, MA-CS and MBI-MA-CS in pH 4.0 by UV spectrophotometer.

Batch	Abs.	Abs.	Abs.	Free mucin (mg)	Absorbed mucin (mg)	SD
CS	0.537	0.542	0.519	0.670	0.330	0.009

## VITAE

Name : Miss. Mullika kongsong  
Date of birth : April 28, 1988  
Nationality : Thai  
Address : 15/2 Moo 4, Nathamtai District, Muang Trang,  
92190

University Education : Bachelor's Degree from Department of Industrial  
Chemistry, Faculty of Applied Science, King  
Mongkut's University of Technology North  
Bangkok, 2006-2009  
Master's Degree from Program of Petrochemistry  
and Polymer Science, Faculty of Science,  
Chulalongkorn University, 2010-2012

Conference attendance: Poster presentation "Synthesis and properties of  
mucoadhesive chitosan-5-amino-2-  
mercaptobenzimidazole for hydrophobic drug delivery system"  
The 9<sup>th</sup> SPSJ International Polymer Conference  
(IPC 2012) "Progress and Future of Polymer  
Science and Technology"
