### Appendix C: Conditions for Adsorption experiments

**Table C** Conditions for Adsorption Experiments

<b>Parameters</b>	<b>Value</b>
Weight of adsorbent packed in adsorber	about 5 g
Operating pressure (const.)	1 atm
Operating temperature (isothermal)	25°C
Humidity of natural gas feed	5-75%RH
Natural gas feed flow rate	
Activated alumina	115.1 ml/min
Molsiv (1/8")	125.8 ml/min
Molsiv (1/16")	138.8 ml/min
Contact time(based on feed flow rate)	
Activated alumina	11.83 sec
Molsiv (1/8")	10.82 sec
Molsiv (1/16")	9.81 sec
Bed volume	24.3 ml

### Appendix D: Conditions for breakthrough curve experiments

**Table D** Multi-layer adsorber

Adsorber layout	Adsorbent type	Height (cm)	Actual volume ratio* (%)
 <p>Bed volume: 75ml</p>	Activated alumina	0.3	3.41
	MolSiv Zeolite type 4A size 1/8"	5.6	63.64
	MolSiv Zeolite type 4A size 1/16"	2.9	32.95
	Ceramic ball	Inert material used as an adsorbent support	

\*PTT Public Co.Ltd.

## Appendix E: Parameters Applied in the Mathematical Model

### E.1 Parameters Applied in the Mathematical Model

**Table E1** Parameters applied in the mathematical model

Parameter	alumina	1/8" 4A Molsiv	1/16" 4A Molsiv
Bed void fraction*, $\varepsilon$	0.37	0.35	0.34
Axial dispersion coefficient**, $D_L$	0.02824	0.027733	0.027170
Bulk density***, (g/cm <sup>3</sup> )	0.73743	0.66529	0.66529

\* Appendix F

\*\* Appendix E.3

\*\*\* UOP information

### E.2 Interstitial velocity

Since the interstitial velocity can be calculated from the correlation,  $v_i = v_s / \varepsilon$ , so the superficial velocity and bed void fraction are needed.

- Superficial velocity

$$v_s = \frac{Q}{A}$$

Where,  $Q = 457.78$  ml/min

$A =$  cross sectional area of adsorber = 8.55 cm

So,  $v_s = 53.52$  ml/min

- Interstitial velocity

$$v_i = \frac{v_s}{\varepsilon}$$

	$\varepsilon$	$v_i$ (ml/min)	contact time(sec)
alumina	0.37	144.65	0.964
molsiv(1/8")	0.35	152.91	18.73
molsiv(1/16")	0.34	157.41	9.42
		all bed	9.83

### E.3 Dispersion Coefficient

- Molecular diffusion coefficient,  $D_m$  is calculated from Chapman-Enskog equation.

$$D_m = \frac{0.0018583T^{3/2}(1/M_A + 1/M_B)^{1/2}}{P * \sigma_{AB}^2 \Omega_{AB}}$$

Where,  $M_A$  = average molecular weight of bulk species (natural gas) = 20.59

$M_B$  = molecular weight of adsorbate species (water) = 18

$\sigma_{AB}$  = collision diameter from Lennard-Jones potential = 3.29352 °A

$\Omega_{AB}$  = collision integral = 1.60089

$P$  = total pressure in atmospheres = 1 atm

$T$  = temperature = 298 K

### Appendix F: Bed void fraction of each adsorbent

The bed void fraction of the adsorbents used in the packed bed adsorber can be obtained from Figure F1.

**Figure F** The porosity as a function of the ratio of particle diameter to bed diameter (Leva, 1947).

### Appendix G: Sensitivity of Overall Mass Transfer Coefficient (k) to the Shape of the Breakthrough Curve

Uttamaroop (2003) indicated the increase of overall mass transfer coefficient resulted in steeper breakthrough curve, and then the  $k$  value of about  $8.5 \times 10^{-5} \text{ s}^{-1}$  was suggested. But in this work, the result obtained from the slope of theoretical breakthrough curve using  $k = 8.5 \times 10^{-5} \text{ s}^{-1}$  was quite different from the experimental one as shown in Figure G1. So, the breakthrough curve from using the  $k$  value of about  $5.0 \times 10^{-5} \text{ s}^{-1}$  was examined, and it was found the breakthrough pattern was similar to the experimental one. But the breakthrough time predicted from the model of  $k = 8.5 \times 10^{-5} \text{ s}^{-1}$  was more precise, with 6.47% error from the experiment. The difference of errors is shown in Table G1. Thus, the breakthrough curve using  $k = 8.5 \times 10^{-5} \text{ s}^{-1}$  was employed for good agreement with the experimental data under identical conditions.

**Figure G** Comparison between the experimental and theoretical breakthrough curves with the influence of the overall mass transfer coefficient at the contact time of 9.83 sec and the feed humidity of 30%RH.

**Table G** Comparison of breakthrough time predicted from several  $k$  value

<b>k value</b>	<b>Theoretical breakthrough time(h)</b>	<b>% Error</b>
5.0 E-05	25	10.07
8.5 E-05	26	6.47

## **Appendix H: Effect of the Bed Voidage on the Breakthrough Time of Deactivated Adsorbents**

The equilibrium adsorption isotherm equations of deactivated adsorbents were applied in the mathematical model to predict the breakthrough profile at the same conditions. From the model, the breakthrough occurs at around 19 hours, resulting in about 20.83 % error from the experiment. Therefore, another parameter related to the adsorbent deactivation inside the packed bed, which is bed voidage, was studied.

The void fraction of deactivated adsorbents were corrected based on the sensitivity analysis of Uttamaroop (2003), which suggested that the theoretical breakthrough curve shifted to the longer time when the bed void fraction decreased. This suggestion was supported with the result from the adsorbents characterization part which when the molecular sieve zeolite were deactivated, the pellets were destroyed, and their size were decreased. Thus, the corrected void fractions for both molecular sieves were applied in the model and gave the good agreement with the experimental data. New void fractions were measured and calculated using data from Appendix F and shown in Table H1. The new breakthrough time was around 22 hours and gave about 8.3% error.

**Table H** The bed void fraction provided in the theoretical breakthrough model for 88.3% deactivated alumina, 15.13% deactivated 1/8” molsiv, and 14.10% deactivated molsiv at the contact time of 9.83 sec and the feed humidity of 30%RH

<b>Adsorbent</b>	<b>Void fraction</b>	<b>Corrected void fraction</b>
alumina	0.37	0.37
1/8” molsiv	0.35	0.30
1/16” molsiv	0.34	0.29

In addition, another parameter that could affect the theoretical breakthrough curve when the void fraction changes is the axial dispersion coefficient because this parameter obtained from calculation by taking into account the void

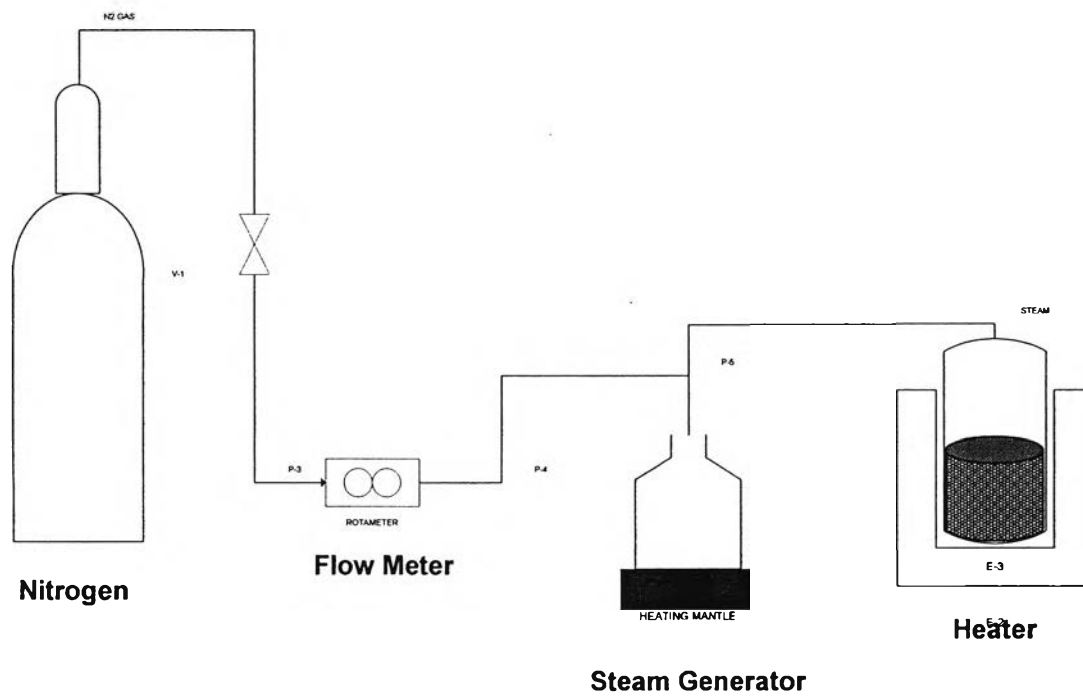

fraction in calculation. But from sensitivity analysis by Uttamaroop (2003), it was found the theoretical breakthrough curve was not sensitive to the change of axial dispersion coefficient. So, the effect of this parameter was not studied in this work.

**Figure H** Comparison between the experimental and theoretical breakthrough curves of deactivated adsorbents at the contact time of 9.83 sec and the feed humidity of 30%RH.

## CURRICULUM VITAE

**Name:** Ms. Wanaporn Khaikham

**Date of Birth:** November 15, 1982

**Nationality:** Thai

**University Education:**

2000-2004 Bachelor Degree of Science (Industrial Chemistry), Faculty of Science, Chiangmai University, Chiangmai, Thailand, with 2<sup>nd</sup> honor.
