KEYWORD: Sericin, Enzymatic hydrolysis, wastewater, Melanogenesis, MITF, Tyrosinase, Reactive oxygen species, Response surface methodology, Alcalase®

Keerati Joyjamras : ANTIOXIDANT WITH ANTIMELANOGENIC ACTIVITIES OF SERICIN HYDROLYSATES OPTIMIZED BY RESPONSE SURFACE METHODOLOGY IN HUMAN MELANIN-GENERATING MNT-1 CELLS.

Advisor: Prof. PITHI CHANVORACHOTE, Ph.D. Co-advisor: Asst. Prof. CHATCHAI CHAOTHAM, Ph.D.

Sericin, a protein presenting in the wastewater from silk industry, causes water pollution and ecological problem. To increase economic value to this waste product, the optimum enzymatic condition that could create sericin hydrolysates with high antioxidant and antimelanogenic capacities was generated through response surface methodology (RSM). Response surface plots demonstrate the major role of temperature on scavenging capacity of sericin hydrolysates assessed via DPPH, FRAP and ORAC assays. Alcalase®-hydrolyzed sericin consisted of sericin-related peptides in differing amounts and smaller sizes compared with unhydrolyzed sericin, as respectively demonstrated by peptidomic and SDS-PAGE analysis. Pre-incubation with 20 mg/mL sericin hydrolysates digested by Alcalase® at RSM-optimized condition (enzyme/substrate ratio: 1.5, pH: 7.5, temperature: 70°C) exhibited higher antioxidant activity against 1 mM hydrogen peroxide in human HaCat keratinocytes and melanin-generating MNT-1 cells when compared with 5 mM N-acetyl cysteine. The lower half maximum inhibitory concentration was 9.05 ± 0.66 mg/mL compared with unhydrolyzed sericin (24.54 ± 0.17 mg/mL) indicated a potent effect of Alcalase®-hydrolyzed sericin on inhibiting melanin production in MNT-1 cells. Not only inhibiting enzymatic activity but also downregulated expression of tyrosinase was evident in MNT-1 cells incubated with 20 mg/mL sericin hydrolysates. Quantitative RT-PCR revealed the decreased mRNA level of MITF, a tyrosinase transcription factor, which correlated with the reduction of pCREB/CREB, an upstream cascade, as assessed by western blot analysis in MNT-1 cells cultured with 20 mg/mL sericin hydrolysates for 12 h. Interestingly, treatment with Alcalase®-hydrolyzed sericin for 6-24 h also upregulated pERK, a molecule that triggers MITF degradation in human melanin-producing cells. The acquired information would facilitate the recycling of waste products from silk industry as an effective antioxidant and antimelanogenic compound.

ACKNOWLEDGEMENTS

The study in Doctor of Philosophy in Pharmaceutical Sciences and Technology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, and this dissertation research would not be complete without the great supervision and support from my advisors, committee members, colleagues, family, and friends.

My deep gratefulness and appreciation would express to my advisor, Professor PITHI CHANVORACHOTE, Ph.D., who provided the great opportunity to study in Ph.D. and to continue research in the interesting field. I would like to warmly thank to Assistant Professor CHATCHAI CHAOTHAM, Ph.D., my co-advisor, for guidance and encouragement support of my research and all stages of this dissertation.

My appreciation is stated to the dissertation committee, including Associate Professor Uraiwan Panich, M.D., Ph.D., Professor WANCHAI DE-EKNAMKUL, Ph.D., Assistant Professor ROSSARIN TANSAWAT, Ph.D., and WANATCHAPORN ARUNMANEE, Ph.D. for their valuable comments and suggestions to improve and construct my dissertation and for providing a memorial moment during my dissertation examination.

Finally, I greatly appreciate to The National Research Council of Thailand (NRCT) through a Research and Researchers for Industries Program, grant no. PHD61I0037 for a financial support of my Ph.D. study and this research.

CHAPTER 1

INTRODUCTION

Background and rationale

The rapid expansion of industries to supply consumable products, globally unavoidably causes of ecological problems (1). Without proper management, sericin protein presenting in the degumming water used in silk processing results in a high level of chemical oxygen demand (COD), which contributes to water pollution (2). In seeking to recycle the wastewater from silk production, several researchers have discovered the potential benefits of silk sericin (3),(4),(5). Silk protein, which is produced from *Bombyx mori*, comprises with 25-30% sericin protein wrapped around fibroin fiber (6). The globular structure of water-soluble sericin consists of diverse amino acids, among which serine, histidine, glycine, threonine, tyrosine, aspartate and glutamine are predominant (3). Recently, several biological functions of sericin have been reported, including antioxidant and anti-tyrosinase activities (7),(8),(9).

Scavenging activity, or the capability to eliminate the unpaired electron in oxygen and other molecules, is one of the major characteristics of antioxidant compounds (10). Through direct interaction with reactive oxygen species (ROS), antioxidants can restrain oxidative stress and prevent the propagation of oxidative

chain reactions, which otherwise damage cellular organelles (11). Moreover, the application of natural antioxidants has been researched in food, pharmaceutical and cosmetic products (12),(13). It is widely accepted that the antioxidant capacity of natural compounds can be accessed through various *in vitro* assays, including 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity, ferric-reducing antioxidant power (FRAP) and oxygen radical absorbance capacity (ORAC) (14). Based on the donation of a single electron to free radicals and ferric ions (Fe^{3+}), antioxidant activity can be respectively determined using DPPH and FRAP assays (15). Despite their simplicity and repeatability, DPPH and FRAP assays carry the drawback of irrelevance to biological ROS and physiological conditions (16). Therefore, ORAC assay, which generates peroxy radicals (ROO^\cdot), is introduced to examine the translocation of hydrogen atoms from antioxidant to oxygen molecules (17). According to diverse mechanisms of action, ROS scavenging activity of antioxidant compounds is recommended to be evaluated through several methods (18),(19),(20).

Intriguingly, the ROS scavenging capacity of peptides, in both natural and hydrolyzed forms, is well established (21),(22),(23). While the antioxidant potential of sericin and sericin hydrolysates has largely been evidenced by DPPH assay (6),(24),(25), the study of scavenging activity of sericin hydrolysates prepared by specific enzymes against diverse free radicals is still limited (26),(27). To optimize conditions in both laboratory and industrial scenarios, response surface methodology (RSM), a type of statistical and mathematical analysis, has been broadly applied (28).

RSM gathers the effects of different independent factors to generate an applicable model for desired output (29). Variables in enzymatic reactions, including pH, temperature and enzyme/substrate ratio are acquired from RSM in this study, and analyzed to discover the optimum conditions for antioxidant activity of sericin hydrolysates assessed via DPPH, FRAP and ORAC assays.

The inhibitory potential of sericin against enzymatic activity of mushroom tyrosinase has been recently indicated (24),(29). Interestingly, anti-tyrosinase activity of sericin and sericin hydrolysates seem to be correlated with their ROS scavenging activity (25). Nevertheless, the effect of sericin hydrolysates on tyrosinase enzyme isolated from human melanin-generating cells has not been investigated. Despite composing of various regulatory proteins, tyrosinase has been considered as a rate limiting enzyme, which catalyzes tyrosine amino acid to melanin pigment in melanogenesis pathway. Thus, tyrosinase inhibitors have been widely accepted as effective depigmenting agents in cosmetic application (30). Not only determining color tone but also protecting skin cells from environmental exposures, especially ultraviolet (UV) radiation which is an important role of epidermal melanin. However, the overproduction of melanin, or hyperpigmented condition, also causes many health problems and aesthetic concerns (31). Large number of available whitening cosmetic products reflects health concern in hyperpigmented condition that affects self-confidence and quality of life. Although, various synthetic and natural

hypopigmenting agents have been continuously introduced but most of them own short efficacy and serious side effects (32).

Melanocytes that located at the bottom layer of epidermis are responsible for melanin production through melanogenesis pathway. The expression of tyrosinase, tyrosinase-related protein-1 (TRP-1) and tyrosinase-related protein-2 (TRP-2 or dopachrome tautomerase; Dct) is regulated by microphthalmia-associated transcription factor (MITF) (33). From the fact that the production of melanin is also mediated by cyclic adenosine 3',5'-monophosphate (cAMP), activation of cAMP results in phosphorylation of cAMP response element-binding protein (CREB), which in turn provokes MITF transcription (34). MITF is also post-translationally modulated by mitogen-activated protein kinase (MAPKs)/extracellular signal-regulated protein kinase (ERK) signal. Activated ERK (pERK) triggers proteasomal degradation of MITF consequence with diminished level of tyrosinase and suppression of melanin synthesis (35),(36). According to regulatory role on tyrosinase expression, MITF has been proposed as a novel target for antimelanogenic compound that could provide sustainable effect on preventing melanin production (37),(38).

This study aims to optimize enzymatic condition for preparation of sericin hydrolysates containing high ROS scavenging activity against various free radicles through RSM compared with unhydrolyzed sericin and known antioxidant. Furthermore, antimelanogenic activity and related mechanisms of RSM-optimized sericin hydrolysates were investigated in human melanin-generating cells. The

obtained information would be benefit for recycling and utilizing sericin, a waste product from the silk industry, as a potent antioxidant and hypopigmenting agent for further development of a safe and effective cosmeceutical products.

Research questions

1. Does an optimum enzymatic condition for preparing sericin hydrolysates possess ROS scavenging capacity against various free radicals obtained from RSM?
2. Does RSM optimized-sericin hydrolysates exhibit antimelanogenic activity via modulating MITF in human melanin-generating cells?

Objectives

1. To optimize condition of enzymatic hydrolysis and ROS scavenging activity of sericin hydrolysates through RSM.
2. To investigate antimelanogenic activity and related mechanisms of RSM optimized-sericin hydrolysates in human melanin-generating cells.

Hypotheses

1. The optimum condition for preparation of sericin hydrolysates containing high ROS scavenging activity against various free radicles could be obtained from RSM.
2. RSM optimized-sericin hydrolysates could inhibit melanin synthesis through regulating on MITF-related proteins.

Expected benefits

1. The optimum enzymatic condition for preparing sericin hydrolysates containing potential ROS scavenging activity against diverse free radicals and biological antioxidant activity.
2. The information of antimelanogenic activity and related mechanisms of sericin hydrolysates for further recycling the waste product from silk industry as a cosmeceutical ingredient.

CHAPTER 2

LITERATURE REVIEWS

Silk sericin protein

Silk is a protein fiber spontaneously synthesized during specific lifetime of various animals, including silkworm and spider. In fabric industry, a silkworm, *Bombyx mori*, is a major source of natural silk production. Silk fiber containing in cocoons, which are derived during the end of larval stage of *Bombyx mori*, comprises with 70-80% fibroin, 20-30% sericin and 1-5% other components, including wax, sugars, minerals and pigments (Figure 1) (39),(40). Fibroin is glycoprotein fiber used for producing silk thread while sericin is protein polymer connecting fibroin filaments and protecting cocoons against environmental stimuli (40). In the degumming step of silk processing, sericin that acts as glue protein wrapping around fibroin will be removed from cocoons by boiling in hot water.

Figure 1 Cross-sectional image obtained from scanning electron microscopy (SEM) of silk fiber presents sericin (solid arrow) linking each fibroin filament (dash arrow) together. (39).

Approximately, 50,000 tons of sericin present as a production waste from silk industry all over the world (41). Without proper management, sericin protein presenting in the degumming water results in a high level of chemical oxygen demand (COD), which contributes to water pollution (2). Recently, sericin from industrial waste can be recovered after separation of low molecular weight impurities via dialysis following with further freeze-drying of the solution containing sericin (42). In seeking to recycle the wastewater from silk production, several researchers have discovered the potential benefits of silk sericin (3),(4),(5).

Structure and amino acid composition of silk sericin

Despite composing of polar amino acids, sericin possesses low water solubility, and forms gel at room temperature. Boiling with hot water ($\geq 50\text{--}60^\circ\text{C}$) during degumming process activates the transformation of β -sheet, which responses for gel forming, into random coil (amorphous) structure of globular sericin that can increase water solubility (3). Sericin contains different 18 amino acids in which 30-39% serine has been considered as one of the identical characters of sericin (Table 1). Additionally, sericin is constructed by 14-16% glycine, 11-15% asparagine acid, and 8-10% threonine (42). Among these amino acids, polar amino acid accounts for 42.3% while non-polar amino acids are about 12.2% (45). Moreover, inorganic constituents, including carbon, oxygen, nitrogen, and hydrogen also present in sericin (3). According to solubility and location surrounding fibroin, sericin can be differentiated into three types of A, B and C (Figure 2). As an adhesive protein, sericin fasten two strands of fibroin for forming silk filament in cocoons. Presenting in the outer layer, sericin A composing of nitrogen, serine, threonine, glycine and aspartic is soluble in boiling water. Sericin B comprising of nitrogen, serine, threonine, glycine, aspartic and tryptophan locates at the middle layer. For the inner layer attaching closely to fibroin is sericin C, which is insoluble and contain nitrogen, sulphur, serine, threonine, glycine, aspartic, tryptophan and proline (45),(46).

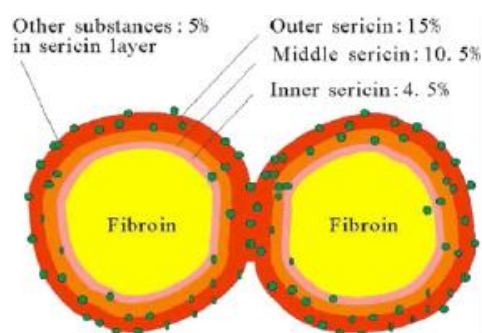

Figure 2 Diagram illustrates sericin layers wrapping around fibroin (40).

* represents essential amino acid

Molecular weight distribution of sericin is variable depending on extraction methods (29),(41). The reported methods for isolating sericin from silk cocoons, include denaturing with boiled detergent or alkaline compounds, enzymatic digestion, steaming, ultrafiltration and infrared ray which present sericin constituents ranged from 10 to 310 kDa (25),(47). Naturally, polypeptide at ~ 400, 250 and 150 kDa have been revealed in silk sericin (42). Teramoto, *et al.* (2005) demonstrated the separated band of protein constituents detected via SDS-PAGE analysis in soluble fraction of sericin at low temperature (Figure 3). Meanwhile, the extraction at high temperature of 121°C provided continuous distribution of sericin proteins range from < 50 to 250 kDa (42). Moreover, the distribution of protein between 5 to 50 kDa had been reported in sericin obtained from spray-drying (45). These modifications of protein distribution pattern could arise from denaturing and transformation of β -sheet to random coil structure during extraction process (48). General information of sericin characteristic is indicated in Table 2.

Figure 3 SDS-PAGE analysis of protein distribution in sericin obtained from 1) water soluble at room temperature, 2) boiling water for 20 min, and 3) autoclave at 121°C for 20 min (41).

Biological activities and applications of sericin

Biological activities and potential therapeutic applications of sericin have been continuously discovered. Recently, cosmetic products containing sericin as an active ingredient are commercially available. These cosmetic preparations highlight sericin as skin moisturizer, sun protectant, antioxidant, brightening agent and anti-aging substance. Not only aesthetic application but also therapeutic potentials, including anti-bacterial, anti-inflammation and anti-cancer as well as biocompatible and biodegradable property bring attention to biological activity of sericin (Figure 4) (3),(49). It is the fact that amino acid constituents and secondary structure resulted from diverse extraction and modification methods critically influence on biological

activities of sericin (3). Gel forming capability and high glycine and serine containing involve with moisturizing property of sericin (44),(50). Sericin at low molecular weight (<100 kDa) possesses high proliferative effect in human fibroblast (51). However, toxic profile of small size sericin is also demonstrated at high concentration (>100 µg/mL) in both normal and cancer cells (51),(52),(53).

Table 2 General characters of silk sericin (42)

Attributes	Properties
Characteristics	White/yellow, water soluble, odor free, and sweet in taste. Moisture content is 10-17%.
Morphology	Wrinkled particles due to collapse of hollow spherical structures on rapid evaluation.
Molecular weight	Ranges from 17100 to 18460 or 90-125 kDa.
Solubility	Insoluble in cold water, soluble in hot water. Solubility increases with addition of polyacrylate and decreases with addition of formaldehyde.
Isoelectric pH	As it contains more of basic amino acids, its isoelectric pH is 4.0.
Sol-gel transition	It gets transformed to fluid at 50-60 °C and returns to gel form on cooling.

Sericin mediates protective effect against UVB-induced cell damage via modulating cellular oxidative stress (54). Intriguingly, greater scavenging activity against reactive oxygen species (ROS) can be achieved after modified structure and component of sericin. Short chain sericin peptide comprising of arginine, valine or

tyrosine indicates the direct inhibition on enzymatic activity of mushroom tyrosinase (55),(29). Moreover, flavonoids and carotenoid presenting in degumming water also involve with anti-tyrosinase activity (29).

Figure 4 Potential applications of sericin from silk cocoons. TE: tissue engineering (48).

จุฬาลงกรณ์มหาวิทยาลัย
CHULALONGKORN UNIVERSITY

Although the immune modulating effect of sericin is still controversial, many biomaterials and drug delivery systems have been developed from sericin (3),(49),(56). According to hydrophilic property and stimulation of collagen synthesis, the benefits of sericin in tissue engineering have been highlighted (3),(57),(58). Response to pH adjustment and composing of OH containing amino acid are principal properties of sericin, which is suitable for drug delivery application (48),(59).

Not only sustain release hydrogel but also conjugation with drugs or other molecules gains attention for development of sericin as drug delivery systems (60),(61),(62),(63),(64).

Furthermore, the benefits of sericin as dietary supplements and food additives are constantly documented. The improvement of glucose and lipid metabolism was demonstrated in high-fat diet rat administrated with sericin (65),(66). Focusing on obesity and cardiovascular disease, supplementation with high sericin containing cocoon extracts significantly reduced plasma cholesterol and triglyceride, and lowered fat weight in high-fat diet mice (67). Surprisingly, very low molecular weight (< 5 kDa) of sericin protein decreased blood pressure through vasodilation (68). It should be noted that chemical reagent as well as extraction and isolation procedure need to be validated for suitable preparation of food grade sericin.

Reactive oxygen species

Reactive oxygen species (ROS) are active substances that highly interact with other molecules consequence with oxidative chain reaction, damaged biological molecules and injured cellular organelles. Both non-free radical and free radical oxygen atom is the active site of ROS. Indeed, reactive nitrogen, reactive sulfur, reactive iron and reactive copper species also play a role in oxidative chain reaction and ROS initiation (69). Despite being harmful at high concentration, low amount of

ROS is essential for mediating cellular signaling pathways. The optimal level of cellular ROS is tightly modulated by intrinsic antioxidant mechanism. As involving in many pathological conditions, the unbalance between generated ROS and cellular antioxidant molecules results in oxidative stress, damaged organelles and eventually cell death (70). Cellular ROS are contributed by endogenous pathways and exogenous stimuli. Exposure to pollutants, toxins, radiations and ozone as well as microbial infections and extensive exercise account for over-production of cellular ROS (71). Superoxide anions ($O_2^{\cdot-}$), hydrogen peroxide (H_2O_2), and hydroxyl radical (OH^{\cdot}) are major endogenous ROS generated during cellular metabolism and oxidative phosphorylation in mitochondria (72). Among these, $O_2^{\cdot-}$ and OH^{\cdot} are considered as free radical due to containing an unpaired electron (70). Superoxide anions are initially generated from oxygen molecules, which act as an electron acceptor in mitochondrial electron transport and from the catalytic enzyme reaction of cytoplasmic xanthine oxidase (Figure 5). Then, superoxide dismutase (SOD) converts $O_2^{\cdot-}$ into H_2O_2 , which is detoxified to H_2O by glutathione-redox system or catalase. However, H_2O_2 is also being a substrate for generating OH^{\cdot} , the most dangerous ROS via Fenton reaction (73),(74),(75). The commonly found endogenous ROS are presented in Table 3 (70).

Table 3 General endogenous ROS (70)

Oxidant	Formula	Reaction Equation
Superoxide anion	$O_2^{\cdot -}$	$NADPH + 2O_2 \leftrightarrow NADP^+ + 2O_2^{\cdot -} + H^+$ $2O_2^{\cdot -} + H^+ \rightarrow O_2 + H_2O_2$
Hydrogen peroxide	H_2O_2	$Hypoxanthine + H_2O + O_2 \leftrightarrow xanthine + H_2O_2$ $xanthine + H_2O + O_2 \leftrightarrow uric\ acid + H_2O_2$
Hydroxyl radical	$\cdot OH$	$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + OH^- + \cdot OH$
Hypochlorous acid	$HOCl$	$H_2O_2 + Cl^- \rightarrow HOCl + H_2O$
Peroxyl radicals	$ROO\cdot$	$R\cdot + O_2 \rightarrow ROO\cdot$
Hydroperoxyl radical	$HOO\cdot$	$O_2 + H_2O \leftrightarrow HOO\cdot + OH^-$

Figure 5 Generation of major cellular ROS (75).

To maintain optimal ROS level, which benefits for biological function, cellular redox status is regulated by enzymatic antioxidant and non-enzymatic antioxidant mechanisms. Despite conversion of $O_2^{\bullet-}$ into H_2O_2 , SOD is classified as cellular enzymatic antioxidant that covers catalase (CAT) and glutathione redox system related proteins, including glutathione peroxidase (GPx) and glutathione transferase (GST) (70),(73). Meanwhile ascorbic acid (vitamin C), α -tocopherol (vitamin E), glutathione (GSH), β -carotene and uric acid are categorized as non-enzymatic antioxidant molecules (76). These non-enzymatic antioxidant molecules directly interact with an unpaired electron on ROS to terminate the oxidative chain reaction (70). Additionally, vitamin C, vitamin E, carotenoids, and flavonoids are exogenous antioxidants, which can be dietary intake from food (77).

Free radical scavenger

At low concentration, antioxidants are the substances that can inhibit or prevent damage induced by ROS (78). Antioxidants possibly modulate oxidative stress through various machineries, including direct interaction with free radicals, suppression of ROS generation and regulation of antioxidant enzymes (79). Generally, free radical scavengers are defined as small molecules that are able to react with ROS and other free radicals via donating hydrogen atom or acceptance of free electron (10),(80). Moreover, ROS scavengers can synergize function of other free radical scavengers and cellular antioxidant (78). According to physical property and

mode of action, ROS scavengers can be classified as water/lipid-soluble and primary/secondary antioxidant. Because of producing stable radicals, the propagation of oxidative chain reaction can be stopped after the interaction between primary antioxidants and ROS. Meanwhile, secondary antioxidants can facilitate antioxidant mechanism via regenerating primary antioxidant (10). Such recycling of ROS scavengers includes the regeneration of active tocopherols (vitamin E), a lipid-soluble antioxidant, from a phenyl radical by a water-soluble antioxidant vitamin C (Figure 6) (79). Additionally, secondary antioxidants are considerably delay and restrain oxidation, and promote activity of metal ions, singlet oxygen, pro-oxidative enzymes and oxidative molecules through redox reactions (10). It should be noted that despite direct interaction with ROS, not all ROS scavengers efficiently provide stable free radical molecule, or stop oxidative chain reaction (80).

Figure 6 Scavenging activity of A) vitamin E, a secondary antioxidant, B) vitamin C, a primary antioxidant, and C) the regeneration of vitamin E from a phenyl radical mediated by vitamin C (79).

Scavenging agents for free radicals and ROS can be intrinsically found in cellular antioxidant such as vitamin C, vitamin E and glutathione, or exogenously obtained from dietary intakes. Recently, therapeutic potentials of free radical scavengers from natural extracts, including plant-derived phenolic compounds and protein hydrolysates obtained from various resources, have been continuously demonstrated (81),(82),(83),(84). These free radical scavengers might compose of aromatic ring in which electron delocalization occurs to create stable free radicals (79).

As mention above, antioxidants (AH) can transfer their hydrogen atom to neutralize free electron presenting in ROS (ROO· and RO·) and free radicals (R·) as following.

Considering the product of antioxidant (A^\cdot), these antioxidant radicals can be inactivated through delocalization of the unpaired electron in aromatic ring, or further accept electron from another free radical to generate non-radical compound as indicated below (85).

According to diverse mechanisms of action, ROS scavenging activity of antioxidant compounds is recommended to be evaluated through several methods (18),(19),(20). It is widely accepted that antioxidant capacities of natural compounds can be accessed through both chemical and biological models. Due to high sensitivity and simple protocol, chemical antioxidant assays are usually performed for screening ROS scavenging activity though there are less relevance to biological ROS and physiological condition. Nevertheless, these assays are required to provide the intrinsic information about free radical scavenging activity of antioxidant compounds. Classification based on scavenging machinery, there are two major

groups of chemical antioxidant assays, including hydrogen atom transfer (HAT) reaction-based assays and single electron transfer (SET) reaction-based assays (10),(79). Antioxidant might eliminate free radicals through both hydrogen donation and transferring electron machinery, however, the major mechanism depends on structure of antioxidant and reaction condition that influences on solubility and partition coefficient of antioxidant (86). Notably, the efficient antioxidant activity also involves with type of ROS, concentration of antioxidant and cellular compartment (87).

Among many free radical scavenging assays, 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity is one of the most recommended assays because of its' simplicity and repeatability (86). In DPPH assay, antioxidant capacity is determined through the capability of transferring electron from stable DPPH free radicals, which are less relevant to biological ROS. Moreover, the inhibitory activity of ROS scavengers against DPPH radicals can be modulated by type of solvent and recentness of DPPH solution (88). Schematic of reaction between DPPH radical and antioxidants (AH) presents in figure 7. It should be noted that antioxidants might also donate hydrogen atom to DPPH radical (89).

Chemical reactions:

where ArOH: phenolic AO

Mechanism of reaction: HAT

Figure 7 Reaction diagram of DPPH assay (90).

Another electron transfer-based assay is ferric-reducing antioxidant power (FRAP) in which capability to reduce ferric ion (Fe^{3+}) to blue colored ferrous (Fe^{2+}) is determined at acidic conditions as indicated in figure 8 (90),(91). Because the reducing power of interested compound is emphasized in testing condition, FRAP assay is commonly used for evaluation of reducing power of biological fluids, foods, and natural extracts (10). Nevertheless, there is less correlation between antioxidant capacity evaluated via FRAP and other chemical assays (86).

Figure 8 Schematic of reaction in ferric-reducing antioxidant power (FRAP) assay,

AH: antioxidant [Adapted from (90)].

Despite their simplicity and repeatability, DPPH and FRAP assays carry the drawback of irrelevance to biological ROS and physiological conditions (16). Therefore, oxygen radical absorbance capacity (ORAC) assay, in which generates peroxy radicals (ROO^\bullet), is introduced to examine the translocation of hydrogen atoms from antioxidant to oxygen molecules (17). Based on donating of hydrogen atom to ROO^\bullet , a major ROS damaging lipid component in food and living organism, antioxidant possessing high inhibition in ORAC assay is suggested to be an effectively biological antioxidant (92). The azo compound of 2'-azobis(2-amidinopropane) dihydrochloride (AAPH) is usually used to generate ROO^\bullet , which in turn interacts with fluorescent prob. Antioxidant will competitively react with ROO^\bullet in order to delay the decomposition of detecting fluorescent probe (Figure 9) (86),(93). However, the ORAC value of food is recently retracted by USDA (United States Department of Agriculture)

because it does not relate with antioxidant capacity *in vivo* model (10). The comparison between DPPH, FRAP and ORAC assay summarized in Table 4.

Figure 9 Reaction diagram of ORAC assay (93).

Table 4 Major chemical-based ROS scavenging assay (10)

Name of assay	Dominating mechanism	Oxidant	Probe	Detection
ROS scavenging assays				
ORAC	HAT	Peroxyl radical generated by AAPH	Fluorescein	Fluorometry
DPPH scavenging	HAT	DPPH radical	DPPH radical	Spectrophotometry or EPR
Redox potential assays				
FRAP	SET	Fe ³⁺	Ferricyanide	Spectrophotometry

Antioxidant peptide

Intriguingly, the ROS scavenging capacity of peptides, in both natural and hydrolyzed forms, is well established (21),(22),(23). It has been revealed that peptide characteristics, including molecular weight, amino acid sequence and hydrophobicity strongly determine its antioxidant potential (94). As a biological macromolecule, protein is one of the targeted molecules damaged by oxidative stress (95). ROS potentially interact with protein at specific amino acids, which can result in both active and stable protein radical. However, antioxidant peptides possess the capability to stabilize free electron and stop oxidative chain reaction (96). Moreover, ROS scavenging capacity of proteins also depends on oxidizable potential of amino acid composition. Among 20 amino acids, nucleophilic sulfur (cysteine and methionine) and aromatic containing amino acid side chains (tryptophan, tyrosine, and phenylalanine) as well as histidine's imidazole-containing amino acids highly interact with free radicals (97). Scavenging activity of amino acids can mediate through both hydrogen atom transfer (HAT) reaction-based assays and single electron transfer (SET). Figure 10 illustrates the ROS scavenging machineries of a) tyrosine b) cysteine and c) histidine containing peptides (98). The amino acids that potentially react with free radicals are also indicated in Table 5.

Figure 10 ROS scavenging machineries of a) tyrosine b) cysteine and c) histidine containing peptides (99).

Not only type of amino acid but also the location presented in peptide sequence determine their antioxidant potency. Either steric property or electron translocation of R-side chain of adjacent amino acid critically influence on free radical scavenging capacity of antioxidant peptide (99). Moreover, solubility of antioxidant peptide or accessibility of solvent also involves with scavenging activity (97). It has been reported that higher ROS scavenging activity of peptides can be achieved through enzymatic hydrolysis modification which reorganizes their tertiary structure, uncovers R-group, and increases solvent solubility (100).

Table 5 Amino acids and their products generated from ROS scavenging activities

(97)

Amino acid	Product	ROS scavenging mechanisms
Cysteine (Cys)	(1) Cystine	(1) Hydrogen abstraction from SH group and subsequent radical dimerization
	(2) Oxy acids	(2) Hydrogen abstraction from SH group, subsequent reaction with oxygen, and isomerization
Methionine (Met)	Methionine sulfoxide	Variety of routes including both radical and non-radical reactions
Tryptophan (Trp)	<i>N</i> -formylkynurenine, kynurenine, 5-hydroxytryptophan, 7-hydroxytryptophan	HO [•] attack or one-electron oxidation of ring
Tyrosine (Tyr)	(1) 3,4-dihydroxy-phenylalanine	(1) HO [•] attack or one-electron oxidation of aromatic ring
	(2) Di-tyrosine	(2) HO [•] attack or one-electron oxidation of tyrosine and subsequent radical-radical dimerization; HOCl
	(3) 3-chlorotyrosine	(3) Chlorination of tyrosine as a result of exposure to HOCl or other chlorinating agents
	(4) 3-nitrotyrosine	(4) Reaction of reactive nitrogen species with tyrosine
	(5) Tyrosine hydroperoxide and subsequent cyclicized materials	(5) Formation of tyrosine phenoxyl radical in presence of O ₂ ^{•-}

Amino acid	Product	ROS scavenging mechanisms
Phenylalanine (Phe)	(1) <i>o</i> -, <i>m</i> -tyrosine	(1) HO [•] attack or one-electron oxidation of aromatic ring. Possibly via reaction nitrogen species
	(2) Dimers of hydroxylated aromatic amino acids	(2) HO [•] attack or one electron oxidation before or after dimerization
Histidine (His)	2-oxo-histidine	HO [•] attack or one-electron oxidation

It should be noted that maximum antioxidant activity of protein hydrolysates requires suitable molecular distribution (26),(43),(101). Additionally, over-reaction of enzymatic hydrolysis also decreases ROS scavenging activity of peptides. Therefore, the conditions of enzymatic hydrolysis need to be optimized for maximizing free radical scavenging activity of protein hydrolysates (100). Some antioxidant peptides prepared from enzymatic hydrolysis are demonstrated in Table 6.

Table 6 Protein hydrolysates containing free radical scavenging activity prepared from various enzymatic hydrolysis (100)

Sources	Enzymes used for production	Activity
Rice endosperm proteins and frog skin	Neutrase	Inhibits auto-oxidation and has hydroxyl radical-scavenging activity
Peanut proteins	Esperase	Prevents LDL oxidation
Peanut proteins, corn gluten, alfalfa leaves	Alcalase	Controls peroxidation and possesses chelating properties
Yam tubers, zein hydrolysate	Pepsin	Contains radical chelating properties and has DPPH-scavenging activity
Sunflower protein	Pancreatin	Shows copper-chelating activity
Peptide from frog skin	Trypsin	DPPH and superoxide scavenger
Animal proteins	Papain	Inhibition of lipid peroxidation
Animal skin	Chymotrypsin	Has DPPH, superoxide and hydroxyl-scavenging activity
Marine sources	Papain, pepsin	Control oxidation and possess strong chelating properties

Hyperpigmented disorder

Color displaying on various organs in human body, including skin, hair and iris is resulted from the accumulation of cellular pigmented compound called melanin. Not only determination of color tone but also protection skin cells from environmental exposures, especially ultraviolet (UV) radiation which is an important role of epidermal melanin (102). People with light skin tone because of low melanin content is more sensitive to develop skin damage, aging and cancer caused by UV radiation compared to dark-skinned person (103). However, the overproduction of melanin or hyperpigmented condition also causes many health problems, especially aesthetic concern (104). Large numbers of available whitening cosmetic products reflects health concern in hyperpigmented condition that affects self-confidence and quality of life. Although, various synthetic and natural hypopigmenting agents have been continuously introduced but most of them own short efficacy and serious side effects (105). Melanocytes that locate at the bottom layer of epidermis are responsible for melanin production through melanogenesis pathway (106).

Melanocytes

After exposure to melanogenic stimuli, melanogenesis or melanin synthesis pathway is started in melanocytes. Melanocytes are cells that play an important role in melanin synthesis. Melanocytes are developed from melanoblasts in the neural crest during embryogenesis (107). Then, they migrate to various organs throughout the body and develop into melanocytes. Melanoblasts that develop into melanocytes can be found in the basal layer (stratum basale) and hair follicles (Figure 11). Melanocytes contain various protein markers such as melanosomal matrix proteins (Pmel17), melan-A or melanoma antigen recognized by T cells 1 (MART-1), tyrosinase, tyrosinase-related protein 1 (TRP-1), dopachrome tautomerase (Dct) or tyrosinase-related protein 2 (TRP-2) and microphthalmia-associated transcription factor (MITF) (108). Melanocyte has a limb-like structure called dendrite that extends into the stratum spinosum, whereas one melanocyte is surrounded by 36 keratinocytes called the epidermal-melanin unit. In melanocyte, production of melanin occurs in melanosome before being transported to neighboring keratinocytes (109). Normally, the color of the skin depends on the shape, size and type of melanosome as well as the distribution of melanosome in the keratinocytes. People with light skin possess the aggregation of small size melanosomes while melanosomes of browned skin are larger size and thoroughly distribute in keratinocyte. Melanin is responsible for filtering and protecting cells from ultraviolet

radiation. In addition, melanocytes can be found in various parts of the body such as the central nervous system, eyes, ears, mucous membranes and hair (108).

Figure 11 Melanocytes located in the basal of skin (106).

Melanogenic signal and regulation

Melanogenesis is a complex pathway occurring in melanosomes. In melanosomes, 2 types of melanin, eumelanin and pheomelanin, are synthesized. Eumelanin is the metabolite of DOPAquinone, which can be integrated with cysteine or glutathione resulting in pheomelanin (Figure 12).

Melanogenesis involves with numerous enzymes including tyrosinase, tyrosinase-related protein 1 (TRP-1), dopachrome tautomerase (Dct) or tyrosinase-related protein 2 (TRP-2). In the first step, tyrosinase enzyme converts tyrosine to L-DOPA, which is further oxidized to DOPAquinone by tyrosinase, again. DOPAquinone is a substrate for generating DOPACHROME that can be transformed into 5,6-dihydroxyindole (DHI) or 5,6-dihydroxyindole-2-carboxylic acid (DHICA). DHI is became

to eumelanin through oxidization by tyrosinase. In addition, Dct converts DOPAchrome into DHICA, which is continuously changed to eumelanin by TRP-1. On the other side, DOPAquinone can be changed to 5-s-cystenyl dopa or glutathionyl dopa in conditions with sulphhydryl donor or with glutathione or cysteine, then becomes pheomelanin (110).

Figure 12 Melanin synthesis pathway (110).

Tyrosinase-related protein family (TRPs) consists of 3 enzymes including tyrosinase, TRP1 and Dct. Despite composing of various regulatory proteins, tyrosinase has been considered as a rate limiting enzyme, which catalyzes tyrosine amino acid to melanin pigment in melanogenesis pathway. Thus, tyrosinase inhibitors have been widely accepted as effective depigmenting agents in cosmetic application (30). Tyrosinase is an enzyme that is important in controlling melanin synthesis. It is an oxidation enzyme that requires copper ion as structural component at the catalytic site and acting as a cofactor. Tyrosinase involves not only with the initial step during conversion of L-tyrosine to L-DOPA and conversion of L-DOPA to DOPAquinone but also the latter of changing DHK to eumelanin. Meanwhile, Dct and TRP1 modulate the final stages of generating DHICA and eumelanin, respectively in melanin synthesis pathway (111).

Microphthalmia-associated transcription factor

The expression of tyrosinase, TRP-1 and Dct is regulated by microphthalmia-associated transcription factor (MITF) (33). MITF is a transcription factor that is important in controlling the growth and development of various cells, including neural crest that will develop into melanocyte. MITF is a member of Myc-related family of basic helix-loop-helix leucine zipper (bHLH-ZIP) that is important in vertebrates. Among several isoforms, the most important isoform is MITF-M, which controls the transcription of tyrosinase, TRP1 and Dct genes, as well as PKC- β

proteins that are responsible for phosphorylation in the tyrosinase structure. After phosphorylation, pMITF binds to DNA with specific codes such as M- (AGTCATGTGCT) and E- (CATGTG) boxes, which are the starting points for transcription of the target genes including tyrosinase, TRP1 and Dct (112). However, pMITF is often unstable and is simply digested by enzymes in proteasome.

Accumulating evidence reveal that MITF is a novel therapeutic target for treatment of hyperpigmented disorders (113). According to mediating tyrosinase expression, suppression on MITF could give more efficacy on preventing melanin production compared with tyrosinase inhibitors (114). Moreover, recent study reports about the potential side-effect of arbutin, an available tyrosinase inhibitor, that highly disintegrate into cytotoxic compound in a presence of water and oxygen molecule (115). The expression of MITF has been reported to be modulated by cyclic adenosine monophosphate (cAMP)-response element binding protein (CREB). The up-regulation of MITF consequence with stimulation of tyrosinase expression and melanogenesis is mediated by phosphorylated-CREB (pCREB) (116). At normal condition, melanogenesis is triggered by the interaction between α -melanocyte-stimulating hormone (α -MSH) and melanocortin 1 receptor (MC1R) receptors. This signal regulates 3',5'-cyclic adenosine monophosphate (cAMP) and protein kinase A (PKA) which in turn promotes CREB to translocate into nucleus (117). Additionally, glycogen synthase kinase 3 β (GSK3 β)/ β -catenin signal also mediates MITF at transcriptional level (Figure 13) (118).

Figure 13 Melanogenesis signaling pathway (118).

After translation, the level of MITF is regulated by mitogen-activated protein kinase (MAPKs)/extracellular signal-regulated protein kinase (ERK) signal. The proteasomal degradation of MITF is promoted after phosphorylation by pERK (35),(36). Therefore, the activation of ERK is one of potential target for suppression tyrosinase expression and inhibiting the process of skin pigmentation (37),(38). Interestingly, the cellular oxidative stress also regulates the melanin production in

melanocyte. The level of cellular reactive oxygen species (ROS) associating with stimulation of extracellular-signal-regulated kinase (ERK) pathway modulates melanogenic function of MITF (119). In a current study, the essential oil from *Achillea millefolium* L. that decreased cellular ROS stimulated the phosphorylation of ERK resulting in the inhibition of melanogenesis (120). Moreover, *Oenothera laciniata* Hill extracts suppresses MITF expression through antioxidant capacity (121). Also, chemical substance that has an inhibitory effect on skin pigmentation through suppression on cAMP mechanism, leading to downregulation of MITF. Sargaquinoic acid (SQA) inhibits melanin production through decrease cAMP level and suppresses tyrosinase in B16F10 mouse melanoma cells (122).

Response surface methodology (RSM)

Base on mathematic and statistical analysis of related experimental information, response surface methodology (RSM) is an effective tool for optimization of processing condition in both laboratory and industrial setting. Indeed, the term of “Response surface methodology” is applied for graphical relationship between variable factors and dependent response derived from mathematical fitting (123),(124). Additionally, both chemical and biochemical machineries can be explained via RSM mathematic model (125). Not only inputting several independent variables at the same time but also depicting interrelation as well as generating of

reliable information is major advantage of RSM (125). To maximize the dependent response or optimize the desired outcome without increasing production cost, a multivariate statistical analysis is implemented in RSM (125). Generally, RSM comprises of three simple steps of 1) Identifying independent factors and their variable levels, 2) Selecting and verifying the RSM experimental model and 3) Determining optimized RSM condition (125).

- 1) *Identifying independent factors and level of variation, an initial and important step for RSM.* The preliminary experiments are essentially required for selecting independent factors and determining the level of variation that critically influence on the interested response. The failure of optimization mostly results from unsuitable selection of variable factors. It is worth noting that because of containing different unit, the variation of independent factors range from -1 to 1 is regularly performed to minimize the relevance of unit parameter. The equation for setting level of variation is indicated as below (125).

$$X = \frac{x - (x_{\max} + x_{\min})/2}{(x_{\max} - x_{\min})/2}$$

where X is the coded variable, x is the independent factor while x_{\max} and x_{\min} are the maximum and minimum values of the independent factor.

2) *Selecting and verifying the RSM experimental model.* A quadratic equation is usually generated from RSM to calculate response variable. A full quadratic equation of secondary model derived from RSM is demonstrated below.

$$y = \beta_0 + \sum_{i=1}^k \beta_i x_i + \sum_{i=1}^k \beta_{ii} x_i^2 + \sum_{1 \leq i < j \leq k} \beta_{ij} x_i x_j + \varepsilon$$

where y is the response variable. β_0 , β_i , β_{ii} and β_{ij} sequentially are regression coefficients for intercept, linear, quadratic and interaction coefficients. X_i and X_j are coded variable of independent factors while ε is the residual associated to the experiments (123).

There are many types of available symmetrical response surface designs that are used for evaluating independent factors. Among these, Box–Behnken design is one of symmetrical second-order experimental designs mostly applied for optimization of chemical and physical processes (123). In comparison with full three-level factorial designs, Central composite design and Doehlert design, Box–Behnken design successfully minimizes number of experiments from 3^k (Full three-level factorial design) and $k^2 + k + c_p$ (Central composite design and Doehlert design) to $2k(k-1) + c_p$; where k is the number of factors and c_p is the number of the central points, which is practically investigated the response variable affected by more than 2 independent factors (Figure 14). Additionally, three interval levels (-1, 0, +1) of all independent factors will be equally modified in Box–Behnken design (122).

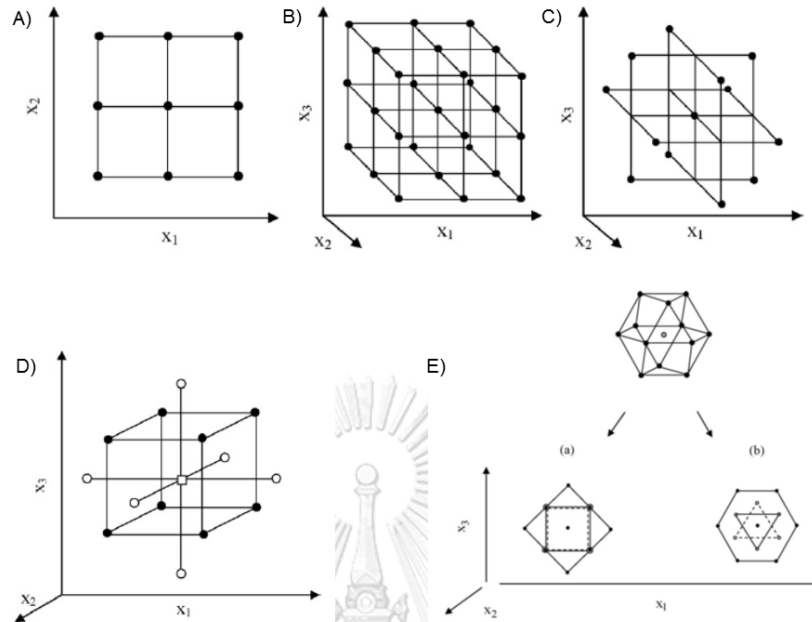

Figure 14 Three-level factorial design for the optimization of (A) two independent factors and three independent factors variables via (B) full three-level factorial design, (C) Box–Behnken design, (D) Central composite design and (E) Doehlert design [Adapted from (123)].

จุฬาลงกรณ์มหาวิทยาลัย
CHULALONGKORN UNIVERSITY

To verify the correlation between RSM model and experimental data, analysis of variance (ANOVA) is performed to evaluate the fitness of quadratic equation of secondary model derived from RSM (123),(125). The value of analysis of variance mostly considered for fitness of RSM mathematical model are summarized in Table 7.

- 3) *Determining optimized RSM condition.* The relation between independent factors and response variable can be simply demonstrated via the response

surface plot. It should be noted that if there are three or more independent factors, the three-dimensional visualization possibly illustrates the relationship between an interested response and two variable factors while the other factors are constant value.

Table 7 Analysis of variance of fitted mathematical model (123),(125).

Analysis of variance	Optimal range	Remark
Residuals	-	Variation from non-independent factors (e.g. fluctuation of measurement)
Lack of fit	$p > 0.05$ (Non-statistical significance)	
Coefficient of determination (R^2)	Nearly 1.000	Adding a variable to the model will always increase R^2
Adjusted R^2	Nearly 1.000	Comparison model with different number of variables
Predicted R^2	Nearly 1.000	-Prediction of new observation -Usually lower than R^2 however over-fit of model is indicated with extremely low predicted R^2
Regression	$p < 0.05$ (Statistical significance)	

Many types of response surface profile are indicated in figure 15. The maximum and minimum response clearly identified inside experimental setting is

respectively illustrated in response surface plot of figure 15A and figure 15D. Although figure 15B demonstrates the point of maximum response in the experimental region, the less relation between the response and x_2 independent factor evidenced with a plateau curve. Figure 15E shows the points of maximum response, minimum response and intermediate response or saddle point within experiment scenario. Meanwhile, the maximum response locating outside the experimental region could be suggested in surface response plot presented in figure 15C (123),(125). It is the fact that only the fitness of the model, but not actual characters of the system can be interpreted from surface response plot (125). To obtain the condition for desirable response, the optimized independent factors can be resulted from the calculation in a quadratic equation of secondary model derived from RSM. Nevertheless, the optimized condition is essentially ranged in the levels of independent factors (123).

Figure 15 Different types of surface response plots including (A) Maximum, (B) Maximum with plateau, (C) Maximum outside the experimental region, (D) Minimum, and (E) Saddle responses (124).

CHAPTER 3

MATERIALS AND METHODS

1. Materials

Lyophilized silk sericin powder was kindly prepared and provided by Ruenmai-baimon, LTD., Surin Province, Thailand. Briefly, sericin protein was extracted by boiling uncover cocoon shells in hot water during the degumming process of the silk industry. Then, the degumming wastewater was lyophilized into dry powder prior kept at 4°C. Porcine pancreas trypsin (EC 3.4.21.4), papain (EC 3.4.22.2), Alcalase from *Bacillus licheniformis* (EC 3.4.21.62), 2,2-diphenyl-1-picrylhydrazyl (DPPH), 2,4,6-tri(2-pyridyl)-s-triazine (TPTZ), ferric chloride hexahydrate ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$), 37% hydrochloric acid (HCl) solution, fluorescein, 2,2'-azobis-2-methyl-propanimidamide dihydrochloride (AAPH), sodium dodecyl sulfate (SDS), Coomassie brilliant blue R-250, isopropanol, ethanol, acetic acid solution, 2',7'-dichlorofluorescein diacetate (DCFH₂-DA), synthetic melanin, bovine serum albumin (BSA), chloroform, 2-propanol, forskolin, 4-butylresorcinol and N-acetyl cysteine (NAC) were purchased from Sigma (St. Louis, MO, USA). A bicinchoninic acid (BCA) protein assay kit, 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium bromide (MTT), Luna Universal qPCR Master Mix, RevertAid First Stand cDNA Synthesis Kit and DNase I were procured from Thermo Scientific (Rockford, IL, USA). MilliporeSigma (Burlington, MA, USA) was the

source of 3% w/w hydrogen peroxide (H₂O₂) solution. N, N, N', N'-tetramethylethylenediamine (TEMED), 40% acrylamide/bisacrylamide 37.5:1, Tween 20 and ammonium persulfate were obtained from Bio-Rad (Hercules, CA, USA). GENEzol reagent was purchased from Geneaid Biotech Ltd. (New Taipei City, Taiwan). Antibodies, including mouse monoclonal antibody to MITF, mouse monoclonal antibody to TRP-1, rabbit polyclonal antibody to Dct and rabbit polyclonal antibody to β -actin were purchased from Abcam (Cambridge, UK). Santa Cruz Technology (Dallas, TX, USA) was a source of mouse monoclonal antibody to tyrosinase. Meanwhile, rabbit monoclonal antibody to CREB, rabbit monoclonal antibody to pCREB (phosphorylated-S133), rabbit monoclonal antibody to Erk1/2, rabbit monoclonal antibody to pErk1/2 (phosphorylated-Thr202/Tyr204), rabbit monoclonal antibody to GAPDH, secondary antibody anti-mouse IgG horseradish peroxidase (HRP)-linked and secondary antibody anti-rabbit IgG HRP-linked were bought from Cell Signaling Technology (Denver, MA, USA).

2. Cell culture

Human keratinocytes (HaCaT) and human melanoma MNT-1 cells were obtained from The American Type Culture Collection (ATCC, Manassas, VA, USA). Human keratinocytes were cultured in Dulbecco's Modified Eagle Medium (DMEM), supplemented with 2 mmol/L L-glutamine, 10% (v/v) fetal bovine serum (FBS) and 100 units/mL of penicillin/streptomycin (Gibco, Gaithersburg, MD, USA). Meanwhile,

human melanin-generating MNT-1 cells were cultured in DMEM supplemented with 20% FBS, 10% AIM-V medium (Gibco, Gaithersburg, MD, USA), 2 mmol/L L-glutamine and 100 units/mL of penicillin/streptomycin. Cells that reached 70-80% confluence under 5% CO₂ at 37°C were used in further experiments.

3. Enzymatic hydrolysis of sericin

Three commercial proteases, including trypsin, papain and Alcalase[®] were chosen to hydrolyze sericin at the optimum conditions recommended by the manufacturers as indicated in Table 8. Briefly, sericin powder was dispersed in de-ionized water at a concentration of 2% w/v. The protein suspension was heated at 95°C for 10 min until complete solubilization before immediate cool down on ice to room temperature. The sericin solution was adjusted to the desired condition depending on used proteases and then hydrolysis experiments were carried out in a 50 mL vessel. To stop the enzymatic reaction, the solution was heated at 100°C for 5 min and quickly chilled on ice to room temperature. After centrifugation at 3,500g for 30 min at 4°C, the supernatant was that were further dialyzed overnight with the phosphate buffer at 4°C before subjected to freeze-drying for collecting the sericin hydrolysates. The hydrolyzed sericin powder was stored at -20°C until use in further experiments.

Table 8 Optimum enzymatic condition following the manufacturer's instructions

Protease enzyme	Factors			
	pH	E/S (w/w)	Temperature (°C)	Time (h)
Alcalase [®]	8	2	60	3
Papain	7	2	60	3
Trypsin	8	2	40	3

E/S: Enzyme/Substrate ratio

4. Response surface methodology for optimization of enzymatic hydrolysis conditions

The three independent variables of pH, enzyme/substrate ratio and temperature at three levels were generated in a Box-Behnken design using a trial version of Design-Expert[®] 11 software (Stat-Ease Inc., Minneapolis, MN, USA). The levels and range of each variable are indicated in Table 9. The response data obtained from each designed condition were determined by the following quadratic polynomial equation:

$$Y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_{11}x_1^2 + \beta_{22}x_2^2 + \beta_{33}x_3^2 + \beta_{12}x_1x_2 + \beta_{13}x_1x_3 + \beta_{23}x_2x_3$$

where Y is the response variable (DPPH, FRAP or ORAC); β_0 is an offset constant; β_1 , β_2 , and β_3 are linear regression coefficients; β_{11} , β_{22} and β_{33} are quadratic effects; β_{12} , β_{13} and β_{23} represent interaction effects; x_1 , x_2 and x_3 represent independent variables in this model.

Table 9 Independent variables and their levels in Box-Behnken

Variables	Code	Factors		
		-1	0	1
pH	A	7	8	9
E/S (w/w)	B	1	2	3
Temperature (°C)	C	50	60	70

E/S: Enzyme/Substrate ratio

The analysis of variance (ANOVA) was performed using RSM software Minitab.16 to determine the adequacy of models through lack of fit value, coefficient determination (R^2) and adjusted- R^2 (126). Statistical significance was $p < 0.05$.

5. Molecular weight distribution of sericin hydrolysates

Constituents of hydrolyzed sericin were analyzed via sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Equal amounts of protein mixed with loading dye were heated at 95°C for 5 min and added onto 12% (w/v) gel of SDS-PAGE. The separated protein constituents were stained overnight with Coomassie brilliant blue R-250 solution. The molecular weight distribution of hydrolyzed sericin was clearly observed after destaining the gel with isopropanol: acetic acid: water (10: 10: 80% v/v) solution (127). Additionally, the size distribution profile of RSM-optimized sericin hydrolysates was also generated through fast protein liquid chromatography (FPLC) coupled with HiPrep 16/60 Sephacryl S-200 HR column (GE Healthcare, Stockholm, Sweden). Briefly, sericin hydrolysates at 4 mg/mL was

prepared in Tris-HCl buffer (50 mM Tris-HCl, pH 8.0, 200 mM NaCl) for loading on the size exclusion chromatography column preequilibrated with Tris-HCl buffer. Then, the protein sample was eluted with Tris-HCl buffer at a flow rate of 1 mL/min. Absorbance of the eluent at 214 nm was determined to estimate protein concentration.

6. Identification of peptide in sericin hydrolysate

Peptidomic analysis was performed at Functional Ingredients and Food Innovation Research Group, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency, Pathum Thani, Thailand through the collaboration with Sittiruk Roytrakul, Ph.D. to identify peptide components in sericin hydrolysates compared to unhydrolyzed sericin.

1) *Liquid chromatography/electrospray ionization-tandem mass spectroscopy (LC-ESI-MS/MS)*

Both sericin hydrolysates and unhydrolyzed sericin was dissolved in 10 mM ammonium bicarbonate. After subjected to zip-tip purification and dried using a speed vacuum concentrator, the protein samples were resuspended in 0.1% formic acid prior to LC-ESI-MS/MS analysis. The protein solutions were injected into an Ultimate3000 Nano/Capillary LC System (Thermo Scientific, Loughborough, UK) coupled to a Hybrid quadrupole Q-ToF impact II™ (Bruker Daltonics GmbH, Bremen, Germany) equipped with a Nano-captive spray ion source. Briefly, 1 µL of peptide

digests were enriched on a μ -Precolumn 300 μm i.d. \times 5 mm C18 Pepmap 100, 5 μm , 100 Å (Thermo Scientific, Loughborough, UK), separated on a 75 μm I.D. \times 15 cm and packed with Acclaim PepMap RSLC C18, 2 μm , 100Å, nanoViper (Thermo Scientific, Loughborough, UK). The C18 column was enclosed in a thermostatted column oven set to 60°C. Solvent A and B containing 0.1% formic acid in water and 0.1% formic acid in 80% acetonitrile, respectively were supplied on the analytical column. A gradient of 5–55% solvent B was used to elute the peptides at a constant flow rate of 300 nL/min for 30 min. Electrospray ionization was carried out at 1.6kV using the CaptiveSpray. Nitrogen was used as a drying gas (flow rate about 50 l/h). Collision-induced-dissociation (CID) product ion mass spectra were obtained using nitrogen gas as the collision gas. Mass spectra (MS) and MS/MS spectra were obtained in the positive-ion mode at 2 Hz over the range (m/z) 150–2200. The collision energy was adjusted to 10 eV as a function of the m/z value. The LC-MS analysis of each sample was done in triplicate.

2) Bioinformatics and data analysis

MaxQuant 1.6.6.0 was used to quantify the peptides in individual samples using the Andromeda search engine to correlate MS/MS spectra to the Uniprot sericin database (128). Label-free quantitation with MaxQuant's standard settings was performed: maximum of two miss cleavages, mass tolerance of 0.6 dalton for main search, unspecific digesting enzyme, oxidation of methionine as variable modifications. Only peptides with a minimum of 7 amino acids, as well as at least

one unique peptide, were required for protein identification. Only proteins with at least two peptides, and at least one unique peptide, were considered as being identified and used for further data analysis. Protein FDR was set at 1% and estimated by using the reversed search sequences. The maximal number of modifications per peptide was set to 5. As a search FASTA file, the proteins present in the sericin proteins downloaded from Uniprot. Potential contaminants present in the contaminants.fasta file that comes with MaxQuant were automatically added to the search space by the software. The level of peptides in each sample were expressed as log₂ value.

7. ROS scavenging assay

1) DPPH radical scavenging activity

DPPH radical scavenging activity of sericin hydrolysates was determined according to the method of Agrawal et al. (129). Briefly, 100 μ L of sericin hydrolysates was mixed with 100 μ L of 0.1 mM DPPH solution in a 96-well plate and incubated at room temperature for 60 min in the dark. The absorbance intensity (Abs) of DPPH radicals was determined using a microplate reader (Anthros, Durham, NC, USA) at 517 nm. The % inhibition of DPPH was calculated as follows:

$$\text{DPPH scavenging inhibition (\%)} = \frac{\text{Abs}(\text{Control}) - \text{Abs}(\text{Sample})}{\text{Abs}(\text{Control})} \times 100$$

2) Ferric reducing antioxidant power (FRAP) assay

FRAP assay was performed to evaluate the ferric reducing antioxidant power of sericin hydrolysates (130). Sericin hydrolysates (50 μL) were allowed to react with 150 μL of 0.3 M FRAP reagent in acetate buffer, pH 3.6 (10 mM TPTZ: 40 mM HCl: 20 mM $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ at 10: 1: 1 ratio). The reaction mixture was kept from light at room temperature for 15 min then the absorbance of ferrous ion (Fe^{2+}) complex was examined using a microplate reader (Anthros, Durham, NC, USA) at 595 nm. A calibration curve of Fe^{2+} was used to calculate reducing power, which is presented as Fe^{2+} equivalence/mg of sericin hydrolysates.

3) Oxygen radical absorbance capacity (ORAC) assay

ORAC assay was performed in 75 mM phosphate buffer (pH 7.4). Briefly, the mixture of sericin hydrolysates (25 μL) and fluorescein solution at final concentration of 70 nM (150 μL) in a 96-well clear bottom black plate was preincubated at 37°C for 15 min. Subsequently, 25 μL of AAPH was rapidly added to the mixture to get the final concentration of 12 mM. The plate was shaken for 5 s before measurement of the fluorescence intensity of fluorescein using a CLARIOstar plus microplate reader (BMG LABTECH, Ortenberg, Germany) with excitation wavelength at 485 nm and emission wavelength at 520 nm every 90 s for 150 min. Instead of the testing solution, phosphate buffer solution (PBS) at pH 7.4 was chosen as a blank, while

Trolox was selected as a calibration solution. Fluorescence measurements were normalized to the curve of the PBS blank. The area under the fluorescence decay curve (AUC) was calculated as follows:

$$AUC = 1 + \sum_{i=150}^{i=1.5} f_i/f_0$$

$$\text{net AUC} = AUC_{\text{antioxidant}} - AUC_{\text{blank}}$$

where f_0 is the initial fluorescence reading at 0 min, f_i is the fluorescence reading at time i min

The regression equation between the net AUC and the Trolox concentration was calculated. ORAC values were expressed as μmol Trolox equivalence (TE)/mg of sericin hydrolysates (130).

8. Determination of cellular ROS level via flow cytometry

Cells seeded at a density of 1×10^5 cells/well in 6-well plates were incubated with $10 \mu\text{M}$ DCFH₂-DA for 30 min at 4°C while kept from light. Then, the cells were washed with PBS and pretreated either with 5 mM NAC, 20 mg/mL Alcalase[®]-hydrolyzed sericin or 20 mg/mL unhydrolyzed sericin prior to exposure to 1 mM H₂O₂. After 30 min of treatment with H₂O₂, the cells were resuspended in PBS and immediately subjected to flow cytometry using Guava easyCyte Benchtop Flow Cytometers (EMD Millipore, Darmstadt, Germany) for measurement of cellular fluorescence intensity of DCF at excitation/emission wavelengths of 488/538 nm.

Cellular ROS level was a relative value of mean fluorescence intensity quantified by Guava InCyte version 3.1 software (EMD Millipore) between specific treatment and untreated control cells.

9. Measurement of melanin content

To evaluate the effect on melanogenesis, the non-toxic concentration range of sericin hydrolysate was determined via MTT viability assay. Melanin-generating MNT-1 cells were incubated with different concentrations of sericin hydrolysate. After 24-72 h, the cells were incubated with 500 µg/ml of MTT solution in PBS (Invitrogen, Carlsbad, CA, USA) for 3 h at 37°C and kept from light. After that, the MTT solution was replaced with DMSO to dissolve the formazan product. The intensity of the absorbance of MTT product was measured at 570 nm using a microplate reader (Anthos, Durham, NC, USA). Cell viability was calculated from absorbance of MTT product, as following equation:

$$\text{Cell Viability (\%)} = \frac{\text{A570 of treatment}}{\text{A570 of control}} \times 100$$

Sericin hydrolysate at concentrations that did not cause significant reduction of %cell viability compared with untreated control cells were selected for further investigation of antimelanogenic activity. Melanin-generating MNT-1 cells were placed in 24-well plates (1×10^5 cells/well) for 12 h, and then the melanin content was

determined after incubation either with non-toxic concentrations of sericin hydrolysate, forskolin (a melanin stimulator) or 4-butylresorcinol (a tyrosinase inhibitor) for 24-72 h (131),(132). Determination of melanin content was slightly modified from previous study (133). Briefly, the collected cell pellets were washed with PBS (pH 7.4) then incubated with 1 N NaOH in 10% DMSO at 80°C for 2 h. Thereafter, the samples were collected and centrifuged at 15,000 rpm for 30 min to separate the supernatant. The absorbance intensity of melanin content in the supernatant was measured at 490 nm using a microplate reader (Anthos, Durham, NC, USA). The melanin content was calculated by interpolating from standard curve of synthetic melanin. The amount of total protein in the supernatant obtained from bicinchoninic acid (BCA) protein assay kit (Thermo Fisher Scientific, Waltham, MA, USA) was used to compare the melanin content/ μg of protein between each sample.

10. Cell-free tyrosinase activity assay

Cell-free tyrosinase activity assay was modified from the previously described method (134). MNT-1 cells were cultured until they reached 70-80% confluence then collected by trypsinization and centrifuged at 5,000 rpm for 5 min at 4°C. The cell pellets were lysed with RIPA buffer containing 1% protease inhibitor cocktail at 4°C and subsequently vortex every 10 min continuously for 1 h. After centrifugation (12,000 rpm for 15 min at 4°C), the supernatant was determined for protein concentration by a BCA assay kit. The sample contains protein 50 μg was incubated

with different concentrations of sericin hydrolysate. After incubation at 37°C for 10 min, added 2 mM of L-DOPA and further incubated for 2 h at 37°C, the resulting of dopachrome was measured using a microplate reader at 490 nm. The tyrosinase activity was calculated as following.

$$\text{Tyrosinase activity (\%)} = \frac{\text{A490 of treatment}}{\text{A490 of control}} \times 100$$

11. Western blot analysis

After indicated treatment, MNT-1 cells were incubated in iced-cold lysis buffer containing 20 mM Tris-HCl (pH 7.5), 150 mM sodium chloride, 10% glycerol, 0.5% triton X-100, 1 mM sodium orthovanadate, 50 mM sodium fluoride, 100 mM phenylmethylsulfonyl fluoride, and protease inhibitor cocktail (Roche Molecular Biochemicals, Indianapolis, IN, USA) for 30 min. Protein concentration was then measured using BCA protein assay kit. Protein 25 ug from cell lysates were separated on 10% SDS-PAGE. Thereafter, proteins were transferred onto a nitrocellulose membrane (Bio-Rad, Hercules, CA, USA). The membranes were blocked with 5% non-fat milk in TBST (25 mM Tris-HCl; pH 7.5, 125 mM NaCl, 0.1% Tween20) for 1 h at room temperature. After washed with TBST for 5 min and incubated with the primary antibody at 4°C overnight, the membranes were washed with TBST for 5 min (3 times) and probed with horseradish peroxidase (HRP) secondary antibody for 2 h at

room temperature. The band of interested protein was illustrated by adding of chemiluminescence substrate (Supersignal West Pico; Pierce, Rockford, IL, USA) onto the membrane after washing with TBST for 5 min for 3 times. The band intensity was quantified using analyst/PC densitometric software (Bio-Rad, Hercules, CA, USA).

12. Quantitative real-time PCR

MNT-1 cells (5×10^4 cells/well) in 6 well-plates were treated with different concentrations of sericin hydrolysate for 24 h. Total RNA from the cells was isolated by using GENEzol™ reagent (Geneaid company, Taipei, Taiwan) according to the manufacturer's instruction. cDNA was synthesized by using RevertAid Premium Reverse Transcriptase (Thermo Fisher Scientific, Waltham, MA, USA). The cDNA obtained was amplified by specific forward and reverse primers (Thermo Fisher Scientific, Waltham, MA, USA) as presented in Table 10.

Table 10 The list of primer used for instigation of melanogenesis

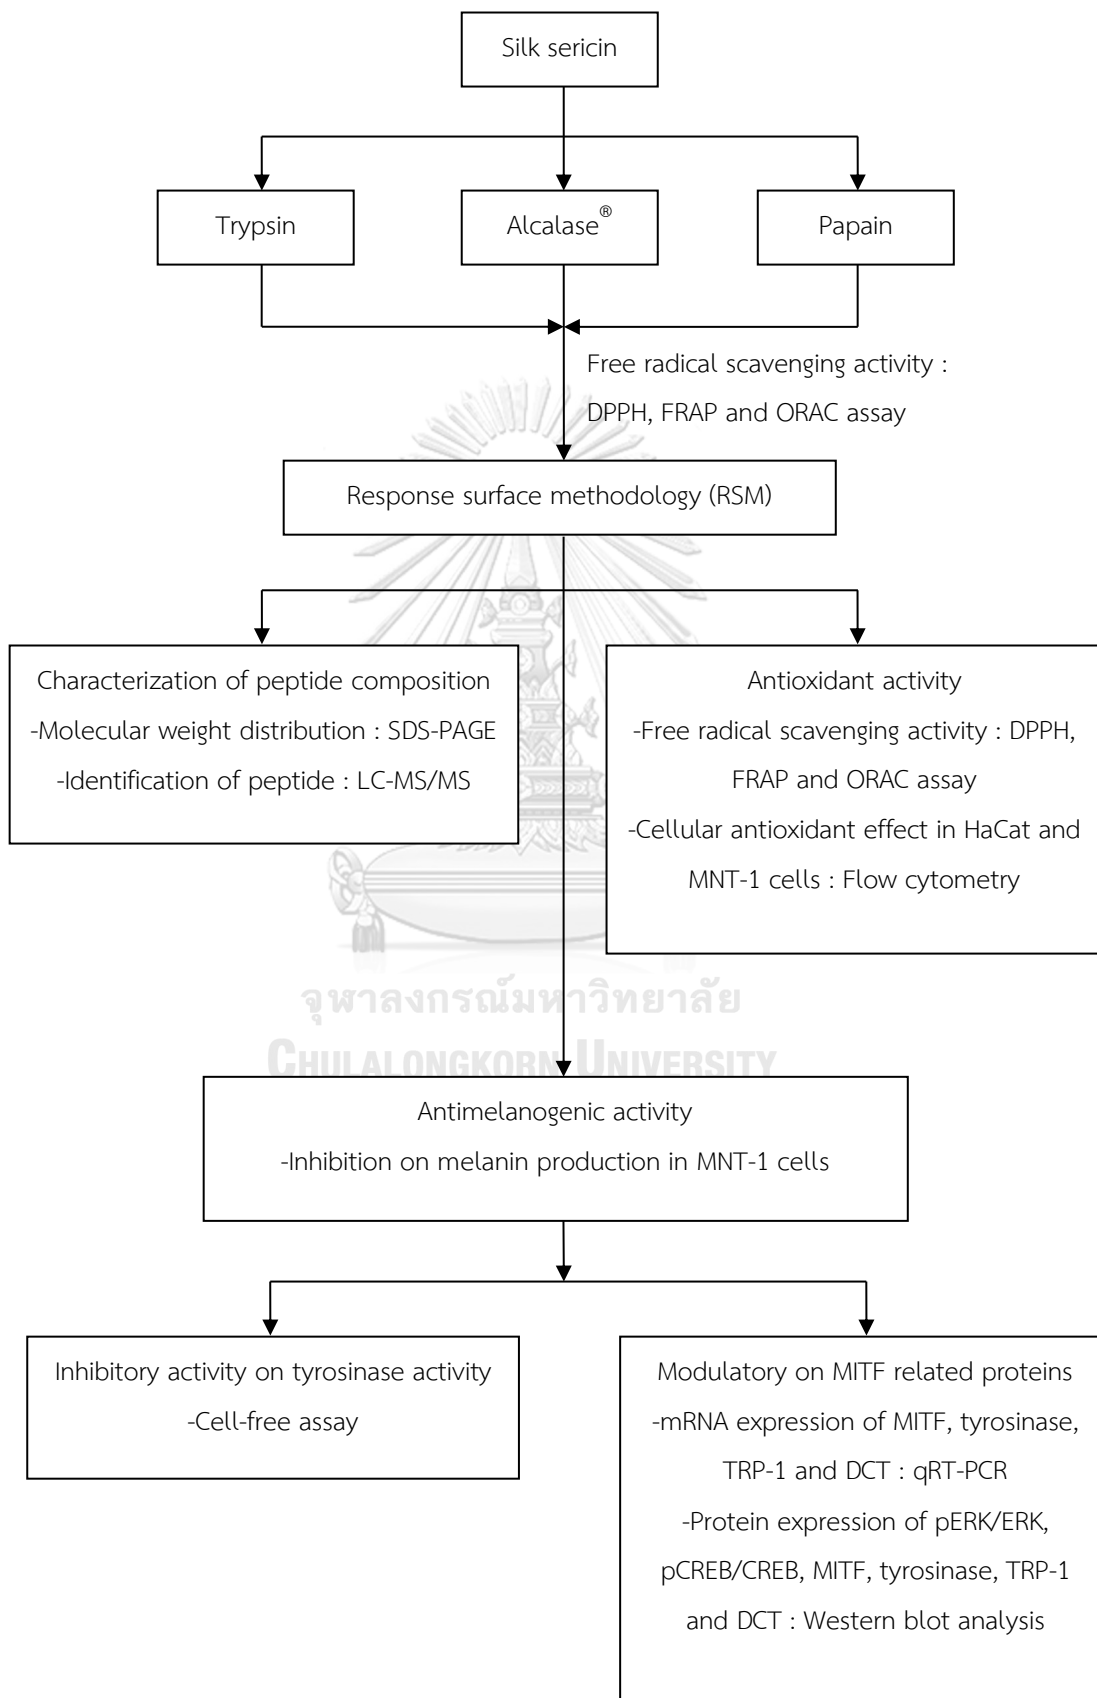

Specific gene	Primer
Human GAPDH	- Forward primer: 5'-GAGTCCACTGGCGTCTTCA-3' - Reverses primer: 5'-TTCAGCTCAGGGATGACCTT-3'
Human MITF	- Forward primer: 5'-TCATCCAAAGATCTGGGCTATGACT-3' - Reverse primer: 5'-GTGACGACACAGCAAGCTCAC-3'
Human tyrosinase	- Forward primer: 5'-TCATCCAAAGATCTGGGCTATGACT-3' - Reverse primer: 5'-GTGACGACACAGCAAGCTCAC-3'
Human TRP-1	- Forward primer: 5'-AAGGCTACAACAAAAATCACCAT-3' - Reverse primer: 5'-ATTGAGAGGCAGGGAAACAC-3'
Human Dct	- Forward primer: 5'-GCAGCAAGAGATACACAGAAGAA-3' - Reverse primer: 5'-TCCTTTATTGTCAGCGTCAGA-3'

Quantitative real-time PCR was performed through a C1000™ Thermal Cycler (Bio-Rad CFX384 real-time pcr system) using Luna® Universal qPCR Master Mix (M3003) (Biolab, Lawrenceville, GA, USA). Reaction combinations were incubated for 39 cycles of 95°C for 5 sec; 60°C for 30 sec and 65°C for 5 sec. The target mRNA expression was determined as the relative comparison established by the ΔC_t method, and the comparative threshold (C_t) of target genes is normalized by β -actin (C_t) values. The mRNA expression was calculated from triplicate experiments from which data represents the means \pm standard deviation (SD).

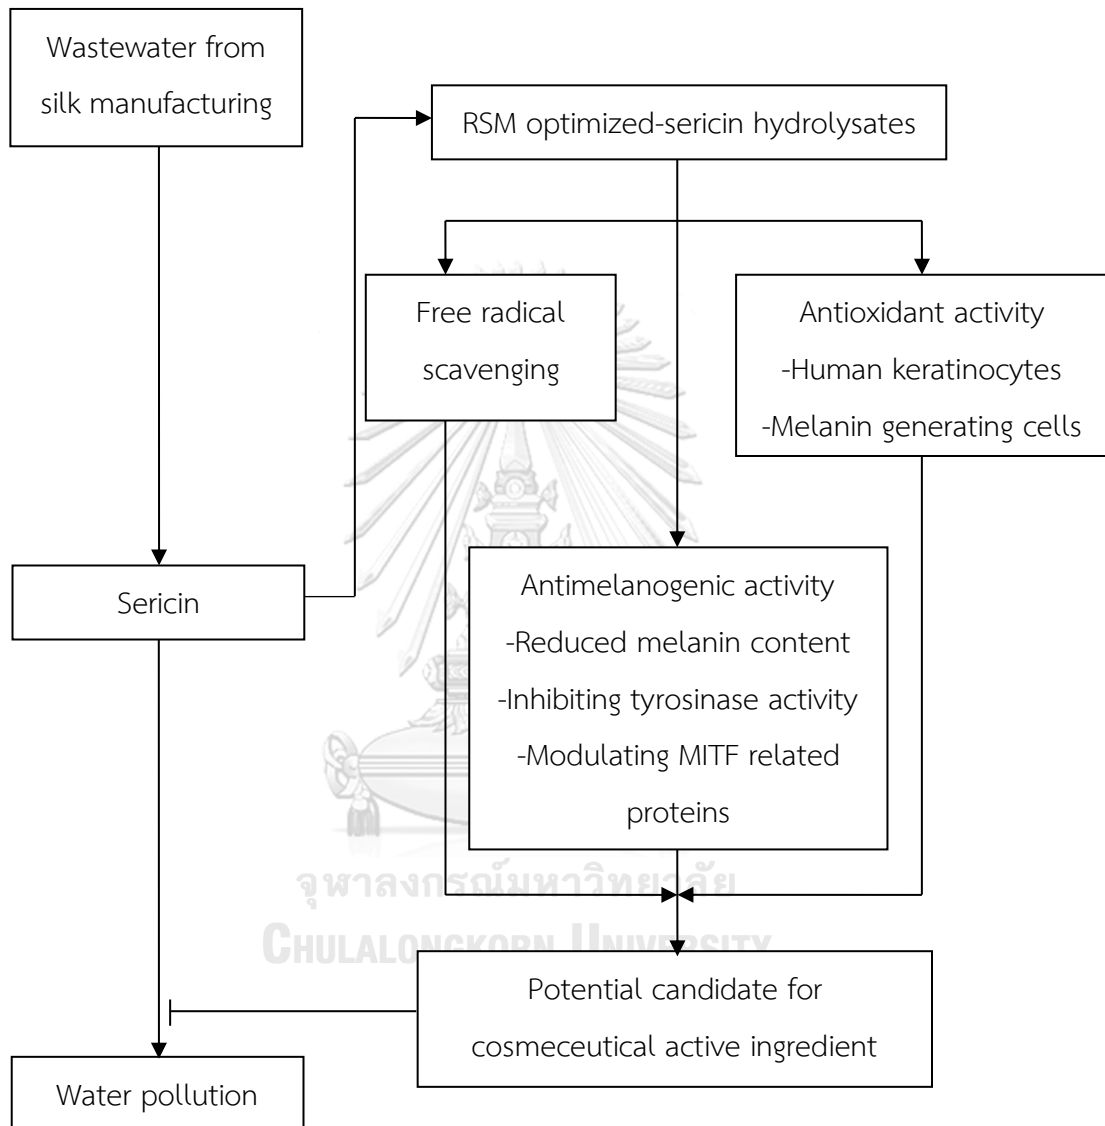

13. Statistical analysis

All experimental data were presented as means \pm standard error of the mean (SEM). SPSS version 22 (IBM Corp., Armonk, NY, USA) with one-way analysis of variance (ANOVA) followed by Tukey's post-hoc test. Any p -value under 0.05 was considered statistical significance.

Experimental design

Research framework

CHAPTER 4

RESULTS AND DISCUSSION

1. ROS scavenging activity of sericin hydrolysates prepared from various protease enzymes

Initially, silk sericin was digested by three commercial proteases to identify the hydrolyzed sericin that possessed the highest antioxidant activity. After 3 h of enzymatic reaction following the manufactures' conditions, SDS-PAGE analysis revealed the alteration of protein constituents in sericin hydrolysates (Figure 16). The absence of high molecular weight (~100–260 kDa) proteins indicated the enzymatic function of Alcalase[®], papain and trypsin in such conditions. Only protein at ~10 kDa was presented in sericin hydrolysates obtained from Alcalase[®] while papain hydrolyzed-sericin consisted with proteins ranging from ~10 to 100 kDa. It should be noted that staining with Coomassie brilliant blue R-250 barely detected protein components in sericin hydrolysates derived from trypsin reaction. Antioxidant activity of the sericin hydrolysates prepared from these three commercial enzymes was then assessed through DPPH, FRAP and ORAC assays. The greater scavenging activity against DPPH and ROO[•] radicals as respectively indicated by greater % DPPH inhibition and ORAC values was noted in all hydrolyzed sericins compared with undigested sericin (Table 11). Interestingly, only sericin hydrolysates obtained from Alcalase[®]

achieved better Fe^{3+} reducing power, as evidenced by its higher FRAP value when compared with unhydrolyzed sericin. It is worth noting that digestion with papain and trypsin decreased Fe^{3+} reducing power of sericin proteins. Sericin hydrolysates obtained from Alcalase[®] demonstrated the highest antioxidant capacity in all ROS scavenging assays (DPPH scavenging activity = $19.71 \pm 0.13\%$, FRAP activity = $435.50 \pm 10.13 \mu\text{mol Fe}^{2+}$ eq./mg protein and ORAC value = $4,383.92 \pm 12.23 \mu\text{mol TE/mg}$ protein). Among the three commercial enzymes, the lowest ROS scavenging activities was observed in sericin hydrolysates obtained by using papain. In summary, Alcalase[®] was selected as the best candidate protease for further optimization of antioxidant activity of sericin hydrolysates.

Figure 16 Distribution of protein composition in sericin hydrolysates prepared from different commercial enzymes in SDS-PAGE analysis.

Table 11 Antioxidant activity of hydrolyzed silk sericin from various proteases

Protease Enzyme	Factors				Response variable		
	pH	E/S (w/w)	Temperature (°C)	Time (h)	DPPH* (% Inhibition)	FRAP value* ($\mu\text{mol Fe}^{2+}$ eq./mg protein)	ORAC value* ($\mu\text{mol TE/mg}$ protein)
- (Unhydrolyzed sericin)	-	-	-	-	9.43 \pm 0.10 ^a	327.50 \pm 11.87 ^a	2,767.72 \pm 30.97 ^a

Data is presented as means \pm SEM (n=3). a-d values with the same letter denote no significant difference in each assay ($p < 0.05$).

* Obtained from three independent experiments

2. Response surface optimization of enzymatic reaction for sericin hydrolysates prepared by using Alcalase[®]

To investigate the influence of enzymatic conditions on the antioxidant activity of sericin hydrolysates, the independent factors, pH, enzyme/substrate ratio and temperature, were resolved by RSM. The experimental conditions and resultant antioxidant activity generated through Box-Behnken design of RSM are shown in Table 12. From the 17 experimental conditions, the antioxidant responses of sericin hydrolysates ranged as follows: % inhibition on DPPH: 11.21–20.37%, FRAP: 362.03–455.93 $\mu\text{mol Fe}^{2+}$ eq./mg protein and ORAC: 3,568.68–4,597.03 $\mu\text{mol TE/mg}$ protein.

Table 12 Box-Behnken factorial design of enzymatic hydrolysis and antioxidant response

Run	Independent variables			Responses		
	A: pH	B: E/S (w/w)	C: Temperature (°C)	Y ₁ : DPPH (% Inhibition)	Y ₂ : FRAP ($\mu\text{mol Fe}^{2+}$ eq./mg sample)	Y ₃ : ORAC (μmol TE/mg sample)
1	9	2	70	14.67	455.93	4,591.43

16	8	1	70	18.31	452.54	4,597.03
17	8	2	60	14.37	449.32	4,064.59

E/S: Enzyme/Substrate ratio, TE: Trolox equivalence

Data were analyzed using model regression analysis with $p < 0.05$ using Design-Expert[®] 11 software. Polynomial equations were as follows:

$$Y1 = 14.5508 - 1.2788A + 0.3292B + 2.3169C - 1.5689AB - 1.5545AC - 0.2932BC \\ - 0.7172A^2 + 0.1325B^2 + 1.4844C^2$$

$$Y2 = 441.784 + 8.4431A - 0.1266B + 33.1675C - 28.7722AB - 0.3609AC - \\ 17.5847BC - 19.3137A^2 - 21.1577B^2 - 9.8212C^2$$

$$Y3 = 4081.7867 + 60.3617A - 119.3904B + 395.0788C + 0.5267AB - 5.5683AC - \\ 97.8541BC + 89.6237A^2 - 74.6771B^2 - 22.1088C^2$$

Where Y1 is the response from DPPH, Y2 is the response from FRAP, Y3 is the response from ORAC, A is pH, B is enzyme/substrate ratio and C is temperature.

Following the statistical analysis of the quadratic model of DPPH (Table 13), FRAP (Table 14) and ORAC responses (Table 15), the significance of all models was evidenced with $p < 0.05$. Additionally, both R^2 and adjusted R^2 ranging between 0.9143 and 0.9988 as well as the non-significance ($p > 0.05$) of lack of fit indicated the high accuracy of predicted responses from these quadratic models [130, 131]. Notably, the predicted R^2 is close to 1 in the quadratic model of response of DPPH (0.8829) and ORAC (0.9870) assays, as presented in Tables 14 and 15, respectively, while the predicted R^2 value is about 0.4991 for FRAP response (Table 14). The positive linear effects of pH (A) and temperature (C) were shown to be significant for scavenging activity determined by DDPH, FRAP and ORAC assays. However, the enzyme/substrate ratio (B) was shown to be clearly positive for DDPH and ORAC, but not for FRAP assay. Or to put it conversely, the quadratic effect of the enzyme/substrate ratio (B^2) only significantly affected ORAC and FRAP responses,

while all ROS scavenging activities were found to be modulated by the quadratic effects of pH (A^2) and temperature (C^2).

E/S: Enzyme/Substrate ratio, * $p < 0.05$

Table 13 also indicates the interactive effect of two variables on scavenging activity against DPPH radicals. The interaction between pH and enzyme/substrate ratio (AB) and between pH and temperature (AC) clearly affected % inhibition of DPPH of sericin hydrolysates prepared from Alcalase[®]. Similarly, significant effects on FRAP antioxidant response arose from pH and enzyme/substrate ratio (AB) interaction as well as enzyme/substrate ratio and temperature (BC) interaction (Table 14). Surprisingly, only the interaction between enzyme/substrate ratio and temperature (BC) was significantly positive on scavenging activity against ROO[•] (Table 15). Taken together, temperature seems to have the greatest influence on ROS scavenging activity of sericin hydrolysates determined by DPPH, FRAP and ORAC assays, as evidenced in multiple linear regression analysis of linear, quadratic and interactive effects.

The effect of correlative adjustment of two variables involved in enzymatic reactions on antioxidant activity of sericin hydrolysates prepared by using Alcalase[®] in DPPH, FRAP and ORAC assays is shown in response surface three-dimension graphs (Figure 17). Correspondence with regression analysis of interactive effect, the major influence of temperature (~70°C) during enzymatic process of Alcalase[®] on all ROS scavenging activities are obviously demonstrated in the correlative alteration with both pH (Figure 17b, e and h) and enzyme/substrate ratio (Figure 17c, f and i). The response surface plots also demonstrate that pH variations combined with variations in enzyme/substrate ratio alter only the % inhibition of DPPH free radicals (Figure 17a), but not Fe³⁺ reducing power (Figure 17d) or oxygen radical absorbance capacity (Figure 17g). Meanwhile, the correlative adjustment of enzyme/substrate ratio with other variables plays a minor role in the modulation of all ROS scavenging capacity.

3. ROS scavenging activity of sericin hydrolysates digested using Alcalase[®] under RSM-optimized conditions

Based on response surface analysis, the optimum conditions for preparation of sericin hydrolysates with maximized antioxidant activity in DPPH, FRAP and ORAC assays was generated through numerical optimization in Design-Expert[®] 11 software. After 3 h of enzymatic reaction performed according to RSM-optimized conditions at pH 7.5, enzyme/substrate ratio of 1.5 (w/w) and temperature of 70°C, sericin hydrolysates were evaluated for ROS scavenging activity. As presented in Table 16, sericin hydrolysates derived after the reaction of Alcalase[®] under the RSM-optimized condition possessed antioxidant activity, including % inhibition of DPPH, Fe³⁺ reducing power and oxygen radical absorbance capacity close to predicted values. It is noted that the lower variation between predicted and observed responses in DPPH and FRAP assays is indicated by lower % error range (between 1.46 and 2.50), compared with the 15.91% error in ORAC response.

Figure 17 Response surface plots depicting the effects of pH, enzyme/substrate ratio (E/S) and temperature on antioxidant activity of sericin hydrolysates prepared by using Alcalase[®] against a-c) DPPH free radicals, d-f) ferric ions (Fe^{3+}) and g-i) peroxy radicals.

Table 16 Antioxidant activity of sericin hydrolyzed by Alcalase[®] under RSM-optimized condition

Optimized condition	Response	Predicted value	Observed value*	% Error
pH: 7.5, E/S: 1.5, Temperature: 70°C Time = 3 h	DPPH (% Inhibition)	19.14	18.65 ± 0.21	2.56
	FRAP ($\mu\text{mol Fe}^{2+}$ eq./mg sample)	455.93	462.31 ± 10.82	1.40

4. Sericin hydrolysates ameliorate H₂O₂-induced oxidative stress in human keratinocytes and melanin-generating cells

The ROS scavenging activity of sericin hydrolysates derived from Alcalase[®] was further evaluated in cell-based assay. Because the potential benefits of sericin are widely recognized in cosmeceuticals (3), the antioxidant activity of sericin hydrolysates obtained from Alcalase[®] was investigated in skin epidermal cells, including human keratinocytes and melanin-generating cells. Flow cytometry histograms illustrate the augmented cellular ROS detected by DCFH₂-DA fluorescence probe in keratinocytes (Figure 18a) and melanoma cells (Figure 18c) after exposure to 1 mM H₂O₂ for 30 min. Intriguingly, preculture with 20 mg/mL of Alcalase[®] sericin

hydrolysates for 1 h dramatically reversed cellular oxidative stress induced by H_2O_2 . The lower relative ROS levels were indicated in the cells preincubated with sericin hydrolysates compared with the pretreatment either with unhydrolyzed sericin (20 mg/mL) or 5 mM NAC, a well-known antioxidant (Figure 18b and d). It is worth noting that RSM-optimized sericin hydrolysates possess greater % inhibition against H_2O_2 in both HaCaT ($99.11 \pm 0.54\%$) and MNT-1 cells ($73.25\% \pm 8.32\%$) compared with unhydrolyzed sericin (HaCaT: $88.52 \pm 2.43\%$, MNT-1: $64.99 \pm 7.83\%$) or NAC (HaCaT: $30.26 \pm 7.62\%$, MNT-1: $51.05 \pm 7.14\%$). These results confirm the antioxidant potential of sericin hydrolysates prepared under RSM-optimized conditions for cosmetic application.

Figure 18 Cellular antioxidant activity of sericin hydrolysates prepared from Alcalase[®] under RSM optimized conditions. The alteration of cellular ROS levels is presented in flow cytometry histograms of (a) human keratinocytes and (c) human melanin generating MNT-1 cells stained with DCFH₂-DA fluorescence probe. Precultures with 5 mM N-acetyl cysteine (NAC), 20 mg/mL unhydrolyzed sericin (UHS) or 20 mg/mL RSM-optimized sericin hydrolysates (SH) obviously diminished the relative ROS levels in (b) human keratinocytes and (d) MNT1 cells after exposure to 1 mM hydrogen peroxide (H₂O₂) for 30 min. Data is presented as means ± SEM from

three independent experiments. * $p < 0.05$ compared with untreated control cells. # $p < 0.05$ compared with the cells treated only with H_2O_2 .

The size distribution profile was also evaluated in sericin hydrolysates prepared under RSM-optimized condition via size exclusion chromatography using FPLC coupling with HiPrep 16/60 Sephacryl S-200 HR column. Like the distribution pattern observed in SDS-PAGE analysis (Figure 19a), the FPLC chromatogram illustrates that RSM-optimized sericin hydrolysates mainly contained with small protein (~0.2–12 kDa) while the mixture of proteins ranging between 0.2 to higher than 150 kDa was presented in unhydrolyzed sericin (Figure 19b). These results suggest that greater antioxidant activity might result from the protein at low molecular weight composing in RSM-optimized sericin hydrolysates.

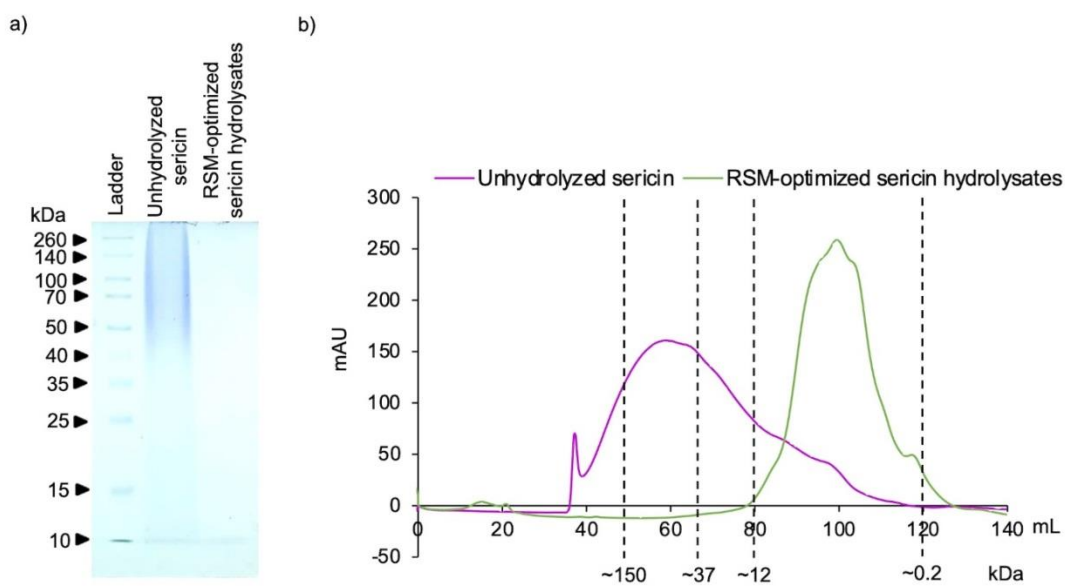

Figure 19 Molecular weight distribution of protein composition in unhydrolyzed sericin and sericin hydrolysates prepared by Alcalase[®] under RSM optimized condition in (a) SDS-PAGE analysis and (b) FPLC coupled with HiPrep 16/60 Sphacryl S-200 HR column.

5. Peptide constituents in sericin hydrolysates digested by Alcalase[®]

The digestion of peptide constituents after enzymatic reaction with Alcalase[®] was further evaluated by LC-ESI-MS/MS compared with native peptides present in unhydrolyzed sericin.

The data obtained from peptidomic analysis indicates the presence of various sericin-related peptides in the unhydrolyzed sericin, which are proteins made from wastewater of the silk industry (Figure 20). Though mostly composed of sericin-derived peptides, the amount of peptide constituents were remarkably different in

the sericin hydrolysates prepared by using Alcalase[®] compared to unhydrolyzed sericin. These results support the alteration of peptide constituents in sericin hydrolysates digested by Alcalase[®].

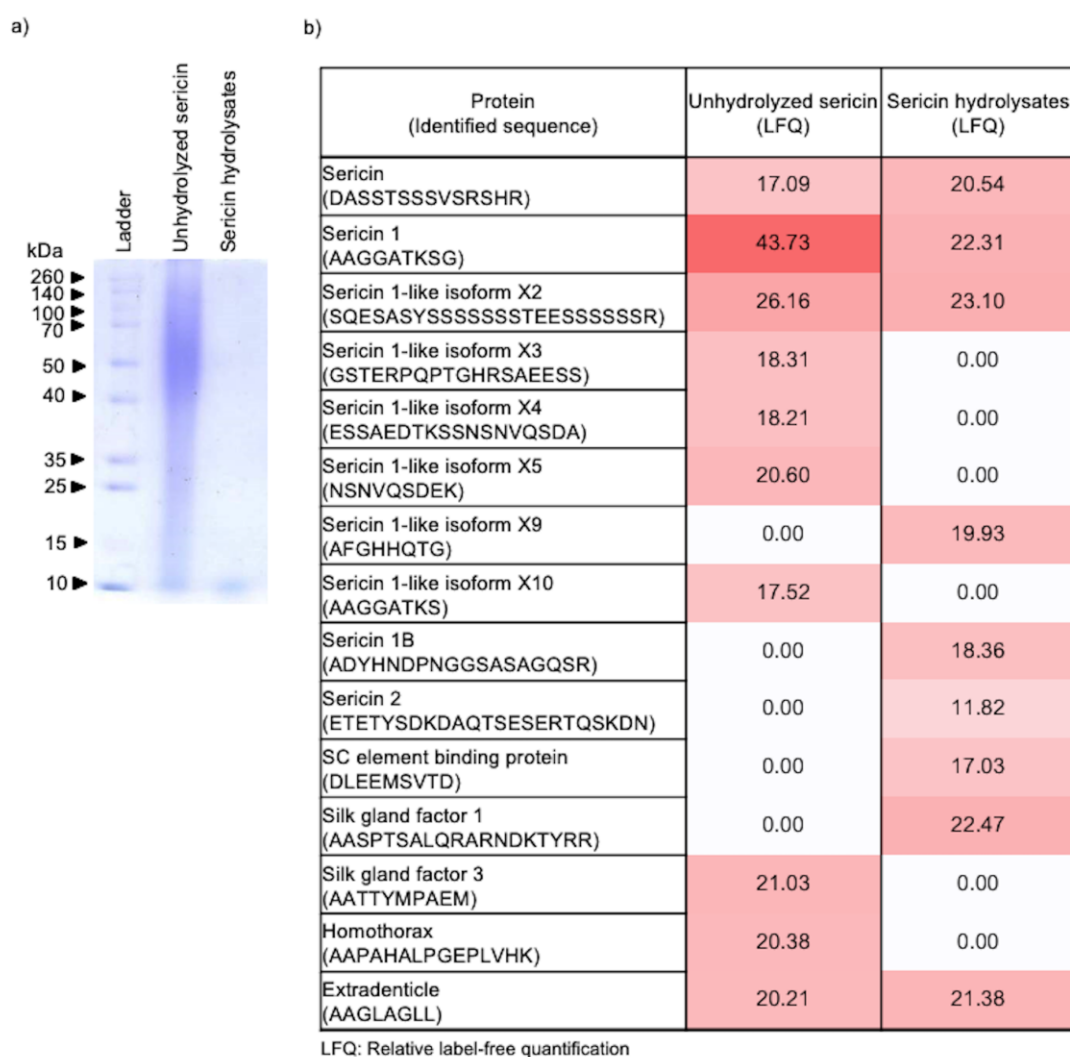

Figure 20 Peptide constituents in sericin hydrolysates prepared by using Alcalase[®]

a) The wide range of peptide distribution from 10 to 260 kDa was demonstrated in unhydrolyzed sericin via SDS-PAGE analysis while only peptide at ~10 kDa contained in sericin hydrolysates prepared by using Alcalase[®]. b) Peptidomic analysis reveals

the alteration of both type and ratio of peptide constituents in sericin after enzymatic digestion by Alcalase[®]. The level of peptides in each sample were expressed as log₂ value.

6. Suppressive effect of sericin hydrolysates on melanin production in human melanin-producing cells

To evaluate the suppressive effect on melanin production, the cytotoxic profile of Alcalase[®]-hydrolyzed sericin was accessed using MTT viability assay. After culture for 24 h, there was no significant change in MNT-1 cell viability following treatment with 1–20 mg/mL sericin hydrolysates compared with the untreated control cells (Figure 21a). The effect on cell proliferation was further examined in MNT-1 cells incubated with Alcalase[®]-hydrolyzed sericin at 0–20 mg/mL for 24–72 h. Despite a 24-h treatment with a considerably non-toxic concentration, sericin hydrolysates (20 mg/mL) notably suppressed proliferation in human melanoma MNT-1 cells over a 48–72-h incubation (Figure 21b). Thus, treatment with Alcalase[®]-hydrolyzed sericin ranging from 0 to 20 mg/mL for 0–24 h was selected as the optimum non-toxic condition for determining antimelanogenic activity in human melanin-producing cells.

Figure 21c shows the gradual increase of melanin production in human melanoma MNT-1 cells after culturing for 6–24 h. The cAMP activator and tyrosinase inhibitor, forskolin and 4-butylresorcinol, were respectively used as positive and

negative controls (131),(132). Surprisingly, incubation for 12 h with either 20 mg/mL sericin hydrolysates or 4-butylresorcinol (20 μ M) comparably decreased cellular melanin content in human melanin-producing cells (Figure 20d). It is worth noting that a dose-dependent reduction of melanin content was observed in MNT-1 cells after a 24-h treatment with sericin hydrolysates at 5–20 mg/mL.

Figure 21 Inhibitory effect of Alcalase[®]-hydrolyzed sericin on melanin production in human melanin-producing cells a) No significant difference of %cell viability was detected via MTT assay after 24-h treatment with 1–20 mg/mL sericin hydrolysates (SH), b) Crystal violet assay indicated low proliferation in human melanoma MNT-1 cells cultured with 20 mg/mL sericin hydrolysates for 48–72 h. c) The cellular

melanin content in MNT-1 cells was gradually increased after culture for 6–24 h in the experiment condition. Tyrosinase inhibitor (TYRinh; 4-butylresorcinol) and forskolin (FSK) were respectively used as a negative control and positive control. d) Sericin hydrolysates prepared by using Alcalase[®] at 20 mg/mL significantly diminished melanin production in human melanin-producing cells promptly at 12-h treatment and sustainably until 24-h of the incubation time. Data is presented as means \pm SEM from three independent experiments. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.005$, **** $p < 0.001$ versus non-treated cells (Ctrl).

The inhibitory effect on melanin production of unhydrolyzed sericin was also performed in human melanoma MNT-1 cells. Compared with sericin hydrolysates prepared by using Alcalase[®] at the same concentration (1–20 mg/mL), higher melanin content was presented in MNT-1 cells cultured with unhydrolyzed sericin for 24 h (Figure 22a). This corresponded with the half maximum inhibitory concentration (IC₅₀) on melanin production in MNT-1 cells shown in figure 22b. The lower IC₅₀ value was demonstrated in sericin hydrolysates at approximately 9.05 ± 0.66 mg/mL compared with an IC₅₀ value of 24.54 ± 0.17 mg/mL for the unhydrolyzed sericin-treated group. Taken together, these results clearly demonstrate the potent inhibitory effect of sericin hydrolysates against melanin production in human melanin-producing cells.

Figure 22 The more potency of Alcalase[®]-hydrolyzed sericin on suppression of melanin production when compared with unhydrolyzed sericin was evidenced by a) the lower cellular melanin content and b) half maximum inhibitory concentration (IC₅₀) in human melanin-producing cells after 24-h of treatments. Data is presented as means ± SEM (n=3). a-b values with the same letters denote no significant difference ($p < 0.05$).

7. Alcalase[®]-hydrolyzed sericin as a human tyrosinase inhibitor

The role as human tyrosinase inhibitor was determined after adding L-DOPA into the cellular lysate prepared from MNT-1 cells that contain tyrosinase with or without Alcalase[®]-hydrolyzed sericin. The formed dopachrome, which represents tyrosinase activity, was reduced in a concentration-dependent manner in the reaction containing 1–20 mg/mL sericin hydrolysates (Figure 23). It should be noted that the significant inhibition of human tyrosinase activity was observed only after incubation with 10–20 mg/mL of sericin hydrolysates. Nevertheless, the results confirm a role of Alcalase[®]-hydrolyzed sericin as an inhibitor against enzymatic activity of human tyrosinase.

Figure 23 The enzymatic function of tyrosinase containing in the cellular lysate from human MNT-1 cells was determined after adding of its substrate, L-DOPA (2 mM) with or without sericin hydrolyzates (SH) prepared by using Alcalase[®]. After further incubation at 37°C for 10 min, Alcalase[®]-hydrolyzed sericin at 10–20 mg/mL significantly inhibited enzymatic activity of human tyrosinase. Data is presented as means \pm SEM from three independent experiments. * $p < 0.05$ versus non-treated cells (Ctrl).

CHULALONGKORN UNIVERSITY

8. Sericin hydrolyzates downregulate tyrosinase expression in human melanin-producing cells

The expression level of tyrosinase, the rate-limiting enzyme in melanogenesis, was further evaluated to clarify the underlying mechanisms of Alcalase[®]-hydrolyzed sericin in human melanin-producing cells. Quantitative reverse transcription PCR revealed that not only tyrosinase mRNA but also MITF mRNA levels, a tyrosinase transcription factor, were downregulated in MNT-1 cells cultured with 20 mg/mL

sericin hydrolysates for 12 h (Figure 24a). Consequently, the decreased levels of both MITF (Figure 24b) and tyrosinase proteins (Figure 24c) were detected by western blot analysis in human melanin-producing cells incubated with sericin hydrolysates (20 mg/mL) for 24 h. It is worth noting that modulation of MITF and tyrosinase expression levels is well-correlated with the antimelanogenic activity of Alcalase[®]-hydrolyzed sericin observed in MNT-1 cells after a 24-h treatment.

Figure 24 Diminution of tyrosinase expression in human melanin-producing cells cultured with sericin hydrolysates a) Quantitative real-time PCR demonstrated the decreased mRNA levels of MITF and tyrosinase (TYR) in human MNT-1 cells cultured with 20 mg/mL sericin hydrolysates (SH) prepared by using Alcalase[®] for 12–24 h. Consequently, protein expression levels of b) MITF and c) Tyrosinase was diminished

*in sericin hydrolysates-treated human melanin-producing cells after 24-h of incubation time. Data is presented as means \pm SEM from three independent experiments. * $p < 0.05$, ** $p < 0.01$ versus non-treated cells (Ctrl).*

9. Alteration of MITF-regulating proteins in human melanin-producing cells cultured with sericin hydrolysates

Based on the decreased expression of MITF mRNA, the modulation of upstream molecules regulating MITF transcription was examined in sericin hydrolysates-treated MNT1 cells. Despite no alteration of pGSK3 β /GSK3 β (Figure 25a) and β -catenin protein levels (Figure 25b), there was a significant reduction of pCREB/CREB expression in MNT-1 cells incubated with 20 mg/mL sericin hydrolysates for 12 h compared with the untreated control cells (Figure 25c). The suppression of pCREB/CREB cascade was correlated with reduced MITF mRNA level in MNT-1 cells following treatment with sericin hydrolysates for 12 h. Because of the remarked decrease of MITF protein expression at 24 h, the role of Alcalase[®]-hydrolyzed sericin on regulatory proteins involved in the post-translational regulation of MITF were examined. Figure 25d shows overexpression of pERK, a signaling molecule that promotes MITF degradation, in human melanin-producing cells incubated with 20 mg/mL sericin hydrolysates for 6–24 h. These results suggest that Alcalase[®]-hydrolyzed sericin mediates MITF expression at both the transcription and post-translational level.

Figure 25 MITF-regulating proteins modulated by sericin hydrolysates prepared by using Alcalase® a-b) There was no alteration of protein involving GSK3 β / β -catenin

*cascade, c) The decreased expression of pCREB/CREB indicated the restraint on upstream signal regulating MITF transcription in human MNT-1 cells incubated with 20 mg/mL sericin hydrolysates (SH) for 12 h. d) Alcalase[®]-hydrolyzed sericin (20 mg/mL) upregulated the expression of pERK, a signaling protein triggering MITF degradation, in human melanin-producing cells after the incubation for 6–24 h. Data is presented as means \pm SEM from three independent experiments. * $p < 0.05$, ** $p < 0.01$ versus non-treated cells (Ctrl).*

Antioxidant peptides have been well recognized for their therapeutic potential and applicable benefits in diverse applications such as food additives and cosmeceutical ingredients (21),(22),(23). Recently, various uses of sericin protein present in the degumming water used in silk processing have been highlighted (3),(4),(5). Silk sericin has potential for use in recycling industrial waste, but it is also potent for biological activity, which inspires the investigation of its antioxidant activity (7),(8),(9),(26). It has been revealed that peptide characteristics, including molecular weight, amino acid sequence and hydrophobicity strongly determine its antioxidant potential (94). Corresponding with the results presented in this study, enzymatic digestion obviously alters the size distribution patterns (Figure 16) and radical scavenging activity of silk sericin protein (Table 11). Due to the possibility of specific scavenging activity being modulated by the definite features of peptide (94), sericin hydrolysates obtained from trypsin and papain enzymatic reactions demonstrated

lower Fe^{3+} reducing antioxidant power compared with both unhydrolyzed sericin and sericin hydrolysates derived from Alcalase[®] (Table 11). It should be noted that maximum antioxidant activity of protein hydrolysates requires suitable molecular distribution (26),(43),(101). Sericin hydrolysates obtained from Alcalase[®] reaction mostly composed with peptides at ~10 kDa meanwhile larger and smaller peptides were respectively found in papain and trypsin hydrolysates (Figure 16). Although the barely detected protein via SDS-PAGE, in which the optimum condition for separating protein needs to be further adjusted in this study, the exclusion chromatography FLPC revealed that Alcalase[®]-hydrolyzed sericin contained with peptides lower than ~ 0.2–12 kDa (Figure 19). The substrate specificity to aromatic amino acids as well as the capability to cleave both terminal and non-terminal peptide bond might involve with the size distribution ranging between ~10–100 kDa in sericin hydrolysates derived from papain (135). Despite being an endopeptidase, high containing of lysine and arginine, the specific substrates for trypsin, in silk sericin protein could result in smaller size of sericin hydrolysates digested by trypsin compared to sericin hydrolysates prepared by Alcalase[®] (136).

Scavenging activity against free radicals, which is one of the important machineries of antioxidant compounds, can be achieved through the translocation of single electrons or hydrogen atoms to free radical molecules (15),(16). Therefore, the antioxidant capability of sericin hydrolysates obtained from three commercial enzymes was evaluated through DPPH and FRAP assays for determination of single

electron donation, as well as ORAC assay for evaluating the translocation of hydrogen atoms herein. When compared with unhydrolyzed, trypsin- and papain-hydrolyzed sericin, Alcalase[®] sericin hydrolysates possessed the highest scavenging capacity against all three free radicals (Table 11). Alcalase[®] is widely used for the enzymatic digestion of various proteins for specific purposes because of its broad substrate specificities and commercial availability (137),(138),(139). The obtained results presented in Table 11 concur with a previous study into the highest % inhibiting DPPH and Fe³⁺ reducing power of sericin hydrolysates derived from Alcalase[®] compared with various protease enzymes (26). In contrast, the reduction of Fe³⁺ reducing power was indicated in trypsin- and papain-hydrolyzed sericin. It is the fact that the less correlation with other antioxidant assays and the underestimating ROS scavenging activity of hydrogen-transferring molecules, especially antioxidant peptide, has been reported as the limitations of FRAP assay (18). Nevertheless, FRAP reducing power is established to represent the capability of antioxidants to maintain cellular redox status and stop oxidative chain reaction in biological sample (88). Taken together with the greater ROS scavenging activity through hydrogen atom translocation assessed via ORAC assay, these data clearly suggest that sericin hydrolysates derived from Alcalase[®] digestion are a candidate for antioxidant peptides through mediating single electron and hydrogen atom transfer.

In order to maximize the antioxidant activity of Alcalase[®] sericin hydrolysates, ROS scavenging activities of sericin hydrolysates released from Alcalase[®] at various

enzymatic conditions were simulated through RSM. Under optimized conditions of pH: 7.5, enzyme/substrate ratio: 1.5 (w/w) and temperature: 70°C obtained from numerical optimization in Design-Expert[®] 11 software, sericin hydrolysates demonstrated scavenging activities assessed through DPPH, FRAP and ORAC assays close to predicted values (Table 16). Response surface models are considered reliable when the response conducted under recommended optimum conditions contains % error from the model-predicted value lower than 5% [140, 141]. For % inhibition of DPPH, the low % error between actual and predicted response of sericin hydrolysates (Table 16) corresponded with the predicted R^2 value obtained from multiple linear regression analysis (Table 13). The predicted R^2 , which is usually lower than R^2 value, is a statistical term presenting the suitability of using a regression model for prediction of a new observed response. Despite having the lowest predicted R^2 value (0.4991) among the three regression response models, the greatest correlation between predicted and conducted responses of FRAP assay was obtained from Alcalase[®] sericin hydrolysates. In contrast, the highest difference from the predicted response of sericin hydrolysates prepared by using Alcalase[®] according to RSM conditions was observed in scavenging activity against $ROO\cdot$ (Table 16). Variations in the ORAC response of sericin hydrolysates might result from the fact that only $ROO\cdot$ scavenging activity can be significantly altered through the digestion of all three variables, pH (A), enzyme/substrate ratio (B) and temperature (C), as

evidenced by p being < 0.05 in linear (A, B and C) and quadratic (A^2 , B^2 and C^2) effects in Table 15.

Notably, the ROS scavenging activities of % DPPH inhibition, Fe^{3+} reducing power and oxygen radical absorbance capacity were comparable between sericin hydrolysates derived from optimized RSM (Table 16) and the manufacturers' recommended conditions (Table 11). The adjustment of pH and/or temperature according to the active enzymatic conditions of Alcalase[®] (pH 6.5-8.5, 60°C) might be considered to minimize the production costs. Because substantial alteration of hydrolyzed proteins was obtained after 3 h of Alcalase[®] enzymatic reaction [137], antioxidant sericin hydrolysates should be achieved after at least 3 h of enzymatic digestion. Additionally, the dramatically augmented antioxidant capacity of sericin hydrolysates in H_2O_2 -treated human keratinocytes and melanoma cells compared with a well-known antioxidant (NAC) and unhydrolyzed sericin (Figure 17) verify its biological activity. It is worth noting that the secondary structures, particularly β -sheet considerably contribute to free radical scavenging activity and cellular antioxidant potential of unhydrolyzed sericin solution though composing mainly of protein at high molecular weight (Figure 19) (48),(140),(141),(142). Indeed, the highest ratio of β -sheet structure was also revealed in the protein hydrolysates prepared by Alcalase[®] compared with various enzymatic digestions (142).

In searching for an effective treatment for hyperpigmented disorders, it is essential to identify compounds that not only exhibit potent efficacy but also have

an acceptable safety profile (32),(143). Recent evidence indicates that MITF, a melanogenic transcription factor, is a novel therapeutic target for modulating melanin synthesis (37),(38). Suppression of MITF correlates with downregulated melanogenesis, a reduction of melanin content, and lightened skin tone (38). While most of available depigmenting agents on the market are tyrosinase inhibitors (30),(144), sericin hydrolysates prepared by using Alcalase® exhibit potent antimelanogenic activity in human melanin-producing cells by acting as human tyrosinase inhibitor (Figure 23) and modulating MITF expression (Figure 24a and b).

Sericin, a natural protein present in degumming water from the silk industry, is recognized for its therapeutic benefits, especially in cosmeceutical applications (48). Nevertheless, a broad peptide composition (~10–250 kDa) hinders sericin from precise therapeutic targeting and lessens its potency (3),(138),(145). Optimal size distribution and specific sequences of amino acids could influence the biological activity of natural proteins (94). Because of the adjustable conditions for producing protein hydrolysates, enzymatic reactions are widely accepted as a method to digest protein structure and composition (146),(147). Among the various proteases, Alcalase®-hydrolyzed proteins exhibited the most promising therapeutic effects (26). As such, the altered pattern of both size (Figure 19a) and peptide component (Figure 20) showed a higher antimelanogenic activity of Alcalase®-hydrolyzed sericin compared with the unhydrolyzed sericin protein (Figure 21). Accounting for the broad substrate specificity, commercial availability (137),(138), and potent antimelanogenic

effects demonstrated in this study, Alcalase[®] could be considerably suitable for enzymatic digestion of sericin proteins.

The greater activity of the sericin hydrolysates could result from smaller-sized peptides, which readily permeate through cell membranes (148). Despite the diverse types of sericin-related peptides, specific peptides identified by peptidomic analysis in Alcalase[®]-hydrolyzed sericin likely play an important role in the suppressive effect on melanin production in human melanin-producing cells. Amino acid constituents in peptides critically modulate the inhibitory activity against enzymatic function of tyrosinase. It has been reported that tyrosinase inhibitory peptides should be composed with arginine and/or phenylalanine for strong binding with tyrosinase and inhibitory activity. Additionally, hydrophobic amino acids such as valine, alanine and leucine as well as aromatic residues of threonine and tyrosine are also essential for the activity of tyrosinase inhibitory peptides (55),(149). The antimelanogenic potential of sericin was discovered through its activity as a mushroom tyrosinase inhibitor (24),(29). Beside composing of various inhibitory amino acids, serine and threonine containing in sericin was proposed to chelate copper at active site, which involves with the capability of melanin synthesis of mushroom tyrosinase (43). Though mushroom tyrosinase is widely accepted for screening of tyrosinase inhibitors (150),(151), the difference of structure and amino acid sequence between human and mushroom tyrosinase could result in variable effect of the candidate tyrosinase inhibitors (152),(153). The inhibitory activity against human tyrosinase associated with sericin-

derived peptides (Figure 23), which was first identified in this study, warrants the further development of sericin hydrolysates prepared by using Alcalase[®] as an effective treatment for hyperpigmented disorders.

Interestingly, the suppressive activities on both the activity (Figure 23) and protein expression of tyrosinase (Figure 24a and c), a rate-limiting enzyme in melanogenesis, indicate the inhibitory effect of Alcalase[®]-hydrolyzed sericin against melanin production observed in human melanin-producing cells after a 12- and 24-h treatment (Figure 21c and d). It should be noted that the modulated mRNA level should be detected prior the alteration of protein expression. A significant reduction of tyrosinase mRNA and its transcription factor, MITF, were demonstrated in MNT-1 cells cultured with 20 mg/mL sericin hydrolysates at 12 h (Figure 24a). This was correlated with the concomitant reduction of protein levels at a later time point (Figure 24b and c).

The upregulated proteins in the MITF-related pathways result in the overproduction of melanin and cellular hyperproliferation (154). Consequently, depigmenting compounds that target MITF effectively reduce melanin content via restraining melanogenesis-regulated proteins and the proliferation of melanocytes (38),(155). Notably, MNT-1 cells are human melanoma and has been used for evaluating melanogenic effects because of its hyperproliferation and hyperpigmented phenotypes (156),(157). The low proliferation (Figure 21b) as well as decreased expression of MITF and tyrosinase in MNT-1 cells incubated with sericin hydrolysates

(Figure 24) demonstrate the high efficacy of Alcalase[®]-hydrolyzed sericin against melanogenesis in human melanin-producing cells.

The modulatory role of sericin hydrolysates prepared by using Alcalase[®] on the upstream signaling cascade that regulates MITF was observed by the reduction of pCREB/CREB level (Figure 25c); however, there was no alteration in the GSK3 β / β -catenin signal (Figure 25a and b). The suppression of pCREB/CREB signaling correlated with decreased MITF mRNA level in human melanin-producing cells after treatment with sericin hydrolysates for 12 h. It should be noted that the gradual increase in pCREB/CREB expression level after a 24-h treatment with sericin hydrolysates may have been the result of a positive feedback mechanism from downstream proteins (158). Despite the recovery of the pCREB/CREB signal at the later time point, the low expression of MITF mRNA and protein was sustained up to 24 h of treatment with Alcalase[®]-hydrolyzed sericin. The protein levels of MITF is post-translationally regulated by pERK through proteasomal degradation (159). The upregulated pERK/ERK pathway in human melanin-generating cells treated with sericin hydrolysates (Figure 25d) would promote the reduction of MITF protein levels concomitantly with downregulated tyrosinase and a reduction of melanin production.

It has been reported that the activation of melanocyte-specific melanocortin-1 receptor (MC1R), a cellular receptor on melanocyte, by α -melanocyte-stimulating hormone (α -MSH), adrenocorticotrophic hormone (ACTH) and agonist stimulating

protein (ASP) upregulates melanogenesis through modulating both and pCREB/CREB and pERK/ERK cascades (106). Therefore, the antagonist effect of Alcalase[®]-hydrolyzed sericin against MC1R is worth for further investigation.

APPENDICES

จุฬาลงกรณ์มหาวิทยาลัย
CHULALONGKORN UNIVERSITY

APPENDIX 1

Relative ROS level in human keratinocyte HaCat cells and melanoma MNT-1 cells precultured with unhydrolyzed (UHS) sericin, sericin hydrolysates (SH), or N-acetyl cysteine (NAC) for 1 h prior exposure to 1 mM hydrogen peroxide (H_2O_2) for 30 min

Treatment	Relative ROS level	
	HaCat	MNT-1
Control	1.00 ± 0.00	1.00 ± 0.00
1 mM H_2O_2	3.56 ± 0.66*	1.48 ± 0.33*
5 mM NAC + 1 mM H_2O_2	2.53 ± 0.13*	0.72 ± 0.19 [#]
20 mg/mL SH + 1 mM H_2O_2	0.03 ± 0.01* [#]	0.39 ± 0.16* [#]
20 mg/mL UHS + 1 mM H_2O_2	0.56 ± 0.26 [#]	0.51 ± 0.21* [#]

Data represent means ± SEM of three independent experiments.

* $p < 0.05$ compared with untreated control cells.

[#] $p < 0.05$ compared with the cells treated only with H_2O_2 .

APPENDIX 2

Percentage of viability in MNT-1 cells assessed by MTT assay after incubation with 0-20 mg/mL sericin hydrolysates (SH) for 24 h

Treatment	Percentage of cell viability
Control	100.00 ± 0.00
1 mg/mL SH	96.23 ± 9.56
5 mg/mL SH	96.54 ± 11.34
10 mg/mL SH	95.73 ± 3.65
20 mg/mL SH	95.08 ± 4.12

Data represent means ± SEM of three independent experiments.

* $p < 0.05$ compared with untreated control cells.

APPENDIX 3

Relative proliferation in MNT-1 cells assessed by crystal violet assay after incubation with 0-20 mg/mL sericin hydrolysates (SH) for 24-48 h

Treatment	Relative proliferation		
	24 h	48 h	72 h
Control	1.00 ± 0.00	1.48 ± 0.02	1.56 ± 0.16
1 mg/mL SH	1.03 ± 0.16	1.37 ± 0.07	1.43 ± 0.24
5 mg/mL SH	1.11 ± 0.06	1.40 ± 0.04	1.40 ± 0.19
10 mg/mL SH	0.98 ± 0.20	1.25 ± 0.09	1.32 ± 0.90
20 mg/mL SH	0.96 ± 0.08	0.99 ± 0.23*	1.00 ± 0.14*

Data represent means ± SEM of three independent experiments.

* $p < 0.05$ compared with untreated control cells at the same time point.

APPENDIX 4

Relative melanin level in MNT-1 cells after incubation with sericin hydrolysates (SH), 4-butylresorcinol or forskolin for 6-24 h.

Treatment	Relative melanin level		
	6 h	12 h	24 h
Control	1.00 ± 0.00	1.14 ± 0.00	1.69 ± 0.14
1 mg/mL SH	1.06 ± 0.21	1.22 ± 0.13	1.48 ± 0.15
5 mg/mL SH	1.03 ± 0.22	1.09 ± 0.08	1.23 ± 0.18**
10 mg/mL SH	0.98 ± 0.12	0.95 ± 0.09	0.95 ± 0.19****
20 mg/mL SH	0.98 ± 0.10	0.45 ± 0.26***	0.60 ± 0.10****
20 µM 4-butylresorcinol	0.70 ± 0.11*	0.57 ± 0.23**	0.61 ± 0.09****
10 µM forskolin	1.36 ± 0.10	2.02 ± 0.12****	2.51 ± 0.12****

Data represent means ± SEM of three independent experiments.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.005$, **** $p < 0.001$ compared with untreated control cells at the same time point.

APPENDIX 5

Percentage of tyrosinase activity containing in the cellular lysate from human MNT-1 cells with various concentrations of sericin hydrolysates (SH)

Treatment	Percentage of tyrosinase activity
Control	100.00 ± 0.00
1 mg/mL SH	85.35 ± 0.78
5 mg/mL SH	71.77 ± 12.35
10 mg/mL SH	56.17 ± 0.05*
20 mg/mL SH	49.97 ± 0.63*

Data represent means ± SEM of three independent experiments.

* $p < 0.05$ compared with untreated control cells.

APPENDIX 6

Relative mRNA levels of MITF and tyrosinase assessed by qRT-PCR in MNT-1 cells cultured with 20 mg/mL sericin hydrolysates (SH) for 6-24 h.

mRNA	Treatment	Relative mRNA level		
		6 h	12 h	24 h
MITF	Control	1.00 ± 0.00	1.91 ± 0.16	2.40 ± 0.47
	20 mg/mL SH	1.23 ± 0.20	0.56 ± 0.23*	1.39 ± 0.43*
Tyrosinase	Control	1.00 ± 0.00	2.96 ± 0.43	2.53 ± 0.41
	20 mg/mL SH	1.77 ± 0.60	0.78 ± 0.34**	1.60 ± 0.10*

Data represent means ± SEM of three independent experiments.

* $p < 0.05$, ** $p < 0.01$ compared with untreated control cells at the same time point.

APPENDIX 7

Relative protein levels of MITF-related proteins assessed by western blotting in MNT-1 cells cultured with 20 mg/mL sericin hydrolysates (SH) for 6-24 h.

Protein	Treatment	Relative mRNA level		
		6 h	12 h	24 h
MITF	Control	1.00 ± 0.00	0.86 ± 0.05	1.26 ± 0.07
	20 mg/mL SH	0.98 ± 0.20	0.75 ± 0.30	0.72 ± 0.15**
Tyrosinase	Control	1.00 ± 0.00	0.81 ± 0.02	1.04 ± 0.21
	20 mg/mL SH	0.79 ± 0.21	0.64 ± 0.04	0.59 ± 0.02*
pGSK3β/GSK3β	Control	1.00 ± 0.00	0.80 ± 0.01	0.88 ± 0.30
	20 mg/mL SH	0.80 ± 0.15	0.82 ± 0.03	0.95 ± 0.05
β-catenin	Control	1.00 ± 0.00	0.83 ± 0.01	0.92 ± 0.27
	20 mg/mL SH	1.00 ± 0.04	0.99 ± 0.03	1.07 ± 0.29
pCREB/CREB	Control	1.00 ± 0.00	1.61 ± 0.24	1.26 ± 0.32
	20 mg/mL SH	1.17 ± 0.08	0.79 ± 0.15*	1.15 ± 0.25
pERK/ERK	Control	1.00 ± 0.00	1.27 ± 0.04	1.33 ± 0.04
	20 mg/mL SH	1.30 ± 0.08*	1.57 ± 0.08*	1.72 ± 0.09**

Data represent means ± SEM of three independent experiments.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.005$, **** $p < 0.001$ compared with untreated control cells at the same time point.

VITA

NAME KEERATI JOYJAMRAS

DATE OF BIRTH 2 March 1985

PLACE OF BIRTH Bangkok, Thailand

INSTITUTIONS ATTENDED

1. 2018 - present
Ph.D. student in Pharmaceutical Sciences and Technology Programme,
Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok,
Thailand
2. 2010 - 2015
Master of Science in Biomedical Sciences,
Faculty of Science, Rangsit University, Pathumthani, Thailand
3. 2003 - 2008
Bachelor of Science in Chemistry,
Faculty of Science and Technology, Valaya Alongkorn Rajabhat University,
Pathumthani, Thailand

HOME ADDRESS 12/327 Moo.4, Beungyitho, Thanyaburi, Pathumthani, Thailand, 12130

PUBLICATION
